Research featuring members of our global society by nature would be complex and necessitate interdisciplinary theoretical frameworks including: 1) science for all; 2) critical feminist theory; 3) a practice of science using inquiry and 4) public policy. Science for all Americans (AAAS, 1989, 1993) call for egalitarian access to science education based on beliefs that all children can learn science. If science is to be for all a research lens using critical feminist theory is appropriate because critical theory does not merely describe a situation, place or practice but attempts to "realize a society that is based on equality and democracy for all its members" (Cohen, Manen and Morrison, p. 28). Researchers would agree that inquiry is defined as a process of posing questions, generating and analyzing data, drawing conclusions, communicating the results, applying the conclusions back to the original question and perhaps following up with a new question (Sandoval, 2005; Cuevas, P., Lee, O., Hart, J., & Deaktor, R, 2005). Science is considered to be one of the most valuable subjects for inclusion of students with exceptionalities because they, like all students, can benefit greatly by the systematic study of the universe with promotion of scientific reasoning and inquiry (Mastropieri & Scruggs, 1992 & 1994; Bell, 2002).

Methodology

This study featured nine students who represent as a group: diverse cultures (Hmong and African-American); second language acquisition (Hmong); special education (LD and EBD) and gifted and talented who attended a public middle school in an urban metropolitan area with 88 percent students of color. An interpretive research design was guided by the following research question (a) What are the experiences of learning and the underlying contexts and structures

for the nine students in their science classrooms? On-site data collection included 19 video taped science teaching and learning episodes across 13 weeks with extensive field notes, individual semi-structured interviews of students (3) and teacher (2) over the course of the research, and examination of student artifacts and projects. The analytic process was based on immersion within the data with repeated sorting, coding, and constant comparison characteristic of the grounded theory method (Morrow & Smith, 1995).

Results

Several important findings illuminate a practice of scientific inquiry that is as varied as the students who make up the class. Inquiry for William and Dion is experienced as fragile and tied to language arts. Their perception of practicing science is that it is more about understanding the words of science and moderated by their academic difficulties that make it seem that all they ever do is have "boring long lectures" or "whole packets to read." For Mai, her practice of science is pragmatic. Her desire is simply to look "good" in the classroom by taking on a "bored" affect about science, getting her work done and "listening to my teacher." Her practice of science is dutiful and devoid of passion and curiosity.

Finally, the practice of science for Dion is dis/abled. At the surface, Dion appears to realize the intent of the reform efforts of science for all, however, taking a closer look at the meaning of these experiences finds that Dion is positioned in this class as dis/abled with an identity that is compromised and negative. His teacher, Maren does many things well. She has high expectations and strong beliefs that all of her students can learn. However, Maren, unintentionally, positions Dion as dis/abled rather than able by assigning other adults to work with Dion and assigning him a front row center seat near the overhead projector where she can keep an "eye" on him. Skrtic (1991) describes this view as a naive pragmatism or "a mode of analysis and problem resolution that is premised on an unreflective acceptance of the assumptions that lie behind social practices" (p. 150). In this case, this naive pragmatism reproduces a status quo for Dion that positions him at a "functional" level and places him within a classroom learning community as dis/abled.

Significance

This study sheds some light on how we might re-imagine what we mean by science for all. First of all, we need to think reflectively as to how we position our more challenging students within the classroom culture. It might be easier to keep an eye on a student by placing him or her front and center, but what message does this present to the other students within the classroom about said students. Secondly, inquiry science still encompasses reading and literacy skills. How can these skills be de-emphasized so that our students with exceptionalities are not excluded from the meaning and intention of an equitable science for all? These findings may help us to design instructional programs that better meet the needs of our complex and diverse classroom populations as we move toward more culturally responsive teaching pedagogies.

PAPER PRESENTATION

Scaffolding teachers in inquiry-based learning and teaching through design

Computer supported Learning Environments, Inquiry learning, Science Education

Alexia Sevastidou, University of Cyprus, Cyprus; Costas Constantinou, University of Cyprus, Cyprus; Eleni Kyza, Cyprus University of Technology, Cyprus

This study explores teachers' ability to make the transfer from inquiry-based learning to inquiry-oriented science teaching. Prior research has demonstrated that teachers encounter many challenges in conceptualizing inquiry-based approaches. The purpose of this study is to give evidence, through the cases of two pairs of pre-service teachers, about constraints and affordances of design-based learning as a method for enculturating teachers in an inquiry-based learning and teaching framework in science. Our research was conducted during a professional development course about new technologies and learning in science. Participants were presented with the task of designing web-based inquiry learning environments on a specific platform that offers tools for reflective inquiry; they received scaffolding for this task through their participation in the course and through their interaction with a web-based teacher learning environment. Data is drawn from two cases of participants who shared similar characteristics, namely in educational background, age and teaching experience, but displayed markedly different performance: one case succeeded in working with relevant scaffolding and in translating challenges with inquiry-based learning into design knowledge; the other case failed to do so. We discuss the implications of this study for efforts to engage teachers in complex design tasks, with the intent to help them grapple with the nature and complexity of inquiry-based pedagogy. Even in the cases where teachers do not find their way around the design task, they gain valuable experiences and insights into inquiry as a teaching and learning framework.

Background

As inquiry-based teaching and learning in science education is increasingly becoming a more consistent paradigm with the needs of today's societies (Sawyer, 2006), exploring ways for introducing teachers in this framework has become a significant task.

Inquiry, the pursuit of open questions, is a fundamental scientific practice, and it is also recognized as a valuable, authentic context for science learning. Required teacher competencies for teaching science as inquiry include scaffolding students in complex tasks like framing questions, grappling with data, creating and critiquing explanations, in some cases, publicly (Crawford, 2007). As reported in prior studies, teachers encounter many challenges in adopting an inquiry learning and teaching framework: they are not prepared for the role of giving students intellectual space as well as structure in open-inquiry approaches; even when they intend to use scaffolding, they hardly listen to students, they tend to be directive, they have trouble in supporting the negotiation of ideas and conceptual evolution and, at the same time, introduce students to inquiry processes (van de Valk & de Jong, 2009; Holbrook & Kolodner, 2000).

Purpose

The purpose of this study was to explore the transfer from teachers' own learning to designing teaching and to identify affordances of a design-based learning approach as a way to scaffold teachers in developing an inquiry-based learning and teaching framework. Our main research questions were: a) what are the challenges that teachers encounter when asked to design an inquiry-based learning environment with scaffolding features? b) How do teachers respond to tools that aim to scaffold their design process?

Method

Participants were ten science teachers enrolled in 13 three-hour sessions of a professional development course about new technologies and learning in science. The course assumed a design-based learning approach and was structured around three key features: a) a design task that engaged teachers in the design of inquiry-based learning environments, b) a design tool, STOCHASMOS, a web-based authoring tool that employs inquiry scaffolding features and c) design scaffolds, provided through a web-based teachers learning environment, in the form of (i) design principles, through the structured presentation of research-derived theoretical and practical information, (ii) prompts for planning and reflecting on the design task and (iii) web-based peer collaboration activities. Throughout the course, participants were grouped in pairs. Each pair developed a web-based inquiry-learning environment, which they submitted as an assignment at the end of the course.

Data collection and analysis

The study used data from multiple sources including: (a) researcher's notes from participants' observations; (b) teachers' written definitions of inquiry; (c) log files recording participants' interactions with the scaffolding provided on the course web-based environment; (d) participants' final learning products, the web-based learning environments that they designed as part of their course work, (e) interviews with teachers after the completion of the course.

Data were analyzed qualitatively using the constant comparative method (Glaser & Strauss, 1967). Different kinds of analyses (e.g. the analysis of the teachers' definitions, the analysis of their final learning product) were synthesized to triangulate findings. In each of these, we tracked the emerging themes for each pair of participants and iteratively compared them to the themes emerging from the analysis of the other pairs.

Findings

The data analysis showed that challenges with inquiry-based learning and teaching were exemplified in the learning environments that teachers designed. Teachers' difficulty in balancing between space and structure was evident in the way they designed scaffolding for students, and in the underlying inquiry patterns on which they structured their environments' activity sequences. Subsequent analysis, which drew on the framework proposed by Quintana et. al (2004), revealed that all pairs followed the same trend in the distribution of the three types of scaffolding prompts across their environments (figure 1,2): process management prompts presented more than the 50% of all prompts provided, reflection and articulation prompts were used at a lower frequency, while sense making prompts were scarcely employed. Teachers seemed to be concerned about the flow of activities and over-emphasized the sequence of steps that students needed to follow; in effect, they often prescribed situations rather than designing opportunities for learning; they used many routine directions as scaffolding prompts, in a way that is inconsistent both with inquiry and with the platform's designer intentions.

Another finding was that four out of five pairs of teachers responded in a common way to the scaffolding provided by the web-based environment: they accessed scaffolding, submitted reflections but did not engage in a constant reviewing process of their design judgments. Data from two cases of participants capture the range of the affordances and constraints of design-based learning as a method of enculturating teachers in an inquiry-based learning and

teaching framework. Even though these two pairs shared similar backgrounds, they had contradicting performances and experiences with design-based learning. According to our analysis pair1 produced the least coherent whereas pair5 the most coherent inquiry-learning environment (table 1). Their experiences with design-based learning are illustrated in the excerpts below:

...we realized that this (design) was a recurring process, although at first we were thinking that we finished with our driving question and so we will move on... somewhere along the process you realize that all stages are interconnected and affect each other, and we returned, reviewed and moved forward (pair5, interview)

...recording our design decisions was not helpful for us...many times we wrote that we will do something and then we found out that it doesn't work. This was stressful. We had to do it because we already described it... (pair1, interview)

Conclusion

The teachers who participated in our design-based learning approach faced similar challenges in designing inquiry-based learning. Four out of five pairs interacted with the reflective scaffolding provided in a similar way. Design as a task was useful in exemplifying challenges with inquiry-based learning and teaching, giving them a more tangible than theoretical character. Being reflective through the whole process of design allowed one pair of teachers to overcome challenges brought about through the design task. As prior research informs us that teachers' ability to teach science as inquiry is affected by the complex interactions of contextual or personal factors, there is further need to explore approaches that engage teachers in reflective practices, like design, as a means of enculturating them with inquiry as a teaching and learning framework.

PAPER PRESENTATION

Exploring the graphical representations in the high-school Earth Science textbooks

Comprehension of Text and Graphics, Instructional Design, Science Education

Yi-Chun Chen-, National Taiwan Normal University, Taiwan, Province of China; Fang-Ying Yang, National Taiwan Normal University, Taiwan, Province of China

By classifying graphical displays, the main purpose of this study is to examine the graphical representations in earth science textbooks used in the senior high school in Taiwan. The material to be analyzed is the tenth-grade earth science textbooks. There are 5 versions of the textbooks. Three versions with highest rates of adoption in schools are involved in the study. Based on previous studies and considering the structure of scientific knowledge (Duschl, 1990), each graphic is classified with respect to its form and content aspects. There are four categories regarding the form of graphical representation: Real Photo, Apparatus Photo, Diagram and Graph. To analyze the content of each graphic, we adopt the goal-of-science hierarchy for teaching science proposed by Duschl (1990). Accordingly, five content categories are applied to the analysis, namely Data, Concept, Relation, Theory and Map or Figure. In so far, we have examined one version of the to-be-analyzed textbooks. Some preliminary findings are presented here. First, it was found that the highest number of the category in form is Graph. Second, regarding the content of graphical representation, our analysis shows that the proportion of each category differs in topics. Considering the first four categories in the content of graphical representation, Concept is dominating in every topic. Such a result implies that concept teaching takes up the highest proportion of the knowledge organization in the textbook. The topic characteristics also affect the proportion of the distribution. The study is still in progress. More findings will be presented in the conference.

Objective

By classifying graphical displays, the main purpose of this study is to examine the graphical representations in earth science textbooks used in the senior high school in Taiwan.

Theoretical Background

According to the constructivist theory of learning, students develop their own understanding by internalizing information either through words or graphics in science textbooks. Words and graphics are different systems of knowledge representation. They differ not only in the displayed form but also in the internal structure. Compared to words, graphics are composed of discrete and easily identified elements that are polymeric or nonnotational (Vekiri, 2002). Paivio's (1986) dual coding theory suggests that verbal information and pictorial information are processed in different cognitive systems and stored in different memory areas (Anderson, 1995). Accordingly, the graphics along with texts would bring about additive effects on learning. The "visual argument" theory also supports that graphics communicate information more effectively in that they insert low demands on working memory (Vekiri, 2002). However, the use of graphics is not always beneficial for the acquisition of knowledge. Schnotz & Bannert (2003) found that reading of graphics is task-dependent, and individual difference must be considered. They argued that graphics

facilitate learning only if individuals have low prior knowledge or if the subject matter is visualized in a task-appropriate way. These dissimilar results may be owing to the problems regarding definitions and entities of graphic representations. In literature, there are few relevant studies (Vekiri, 2002). Thus in the study, an attempt is made to examine the graphical representations in the high-school earth science textbooks.

Methodology

Material The material to be analyzed is the tenth-grade earth science textbooks. There are 5 versions of earth science textbooks used in the senior high schools in Taiwan. Three versions with highest rates of adoption in schools are involved in the study. Currently, four topics related to "Global Warming" are being analyzed, including Atmosphere, Ocean, Natural Hazard and Climate Change. **Method** Based on previous studies and considering the structure of scientific knowledge (Duschl, 1990), each graphic is classified with respect to its form and content aspects. The classification details are interpreted as follows:

1.The form of graphical representation There are four categories regarding the form of graphical representation: Real Photo, Apparatus Photo, Diagram and Graph. Apparatus Photo means that the graphic is photo taken by equipments such as telescope, microscope, satellite and so forth. In other words, it can't be read by raw eyes (Real Photo). Diagram is the part, structure, simulation or operation of real objects, abstract entities or processes (Vekiri, 2002). The water cycle and the formation process of a typhoon belong to this category. Graph is the relation, sequence, statistics or values showing how two or more variables are related to each other. Noticeably, some textbook authors used more than one form in creating graphics.

2.The content of graphical representation To analyze the content of each graphic, we adopt the goal-of-science hierarchy for teaching science proposed by Duschl (1990). The bottom of the hierarchy is data collection where all science investigations begin. After collecting sufficient data, scientists would seek the lawlike relationships or patterns in collected data to develop science theory. The process is a rational feedback loop which suggests that scientific theory is subject to change. New theories would either emerge from different interpretations on existing data because of the development of new technology or from newly found data. In either case, the theory development restarts from data collection. Based on the hierarchy, the content of graphics was sorted into five categories, namely Data, Concept, Relation, Theory and Map or Picture. The first four categories are adopted from the themes of the goal-of-science hierarchy. Notably, since in textbooks, data are usually presented to students in lawlike patterns, Relation in our coding scheme indicates the relation between science concepts. The category of Map or Picture is an additional category. According to Vekiri (2002), Map is the feature (or data) and their location (or distribution) in real territory while Picture shows people, objects or scenes. Each graphic is allowed to be assigned to more than one category if necessary. Data analyses After coding, descriptive and Chi-square analyses are employed for further statistical analysis.

Results and Discussion

The study is still in progress. In so far, we have examined one version of the to-be-analyzed textbooks. Some preliminary findings are presented here. As shown in Table 1, numbers of graphics in each topic are not equally distributed. Across the four topics, the highest number of the category in form is Graph, followed by Diagram, but in the topic of Natural Hazard, it is Apparatus Photo (25.00%) coming in the second place. Regarding the content of graphical representation, our analysis shows that the proportion of each category differs with topics. For instance, Map or Picture is most frequently seen in Natural Hazard but in Atmosphere, it is Concept that appears most often. Besides, different topics have different scopes and aims. For example, in the topic of Natural Hazard, the textbook is full of real disaster photographs, satellite photographs, weather map etc. Whereas, the topic of Atmosphere and Ocean focuses more on illustrating relevant concepts. Considering the first four categories in the content of graphical representation, Concept is dominating in every topic. The result implies that concept teaching takes up the highest proportion of the knowledge organization in the textbook. The topic characteristics also affect the proportion of the distribution. For example, the percentage of Theory in Climate Change is higher than those in other three topics because theories about climate change are by nature uncertain. Consequently, a lot of graphics in this topic are devoted to making predictions and building theoretical models. As mentioned before, some graphics may carry more than one category of form or content. Table 2 shows the numbers of categories found in individual graphics as well as their counts and proportions. In the form aspect, no more than 2 categories are ever found in one graphic while there might be up to four categories found in the content of a graphic. As seen in the Table 2, Climate Change and Natural Hazard have the highest variety in the number of categories. The results suggest that since the two topics deal with multi-dimensional problems, the use of multiple representations in graphics is necessary to convey relevant knowledge.

PAPER PRESENTATION

The Speed of Data Extraction from Decorated Graphs

Irit Aharon, University of Hifa, Israel; Billie Eilam, Faculty of Education, University of Haifa, Israel

Quantitative graphics combine quantitative information with pictorial elements. One example is the decorated graph, commonly used for communicating quantitative information in mass media and school textbooks. This prevalent mode of representing information calls for the examination of possible effects of decorative pictorial elements on individuals' ability to read the graph. Therefore, the present study investigated students' response time, required for extracting simple data from different types of decorated graphs. Participants comprised 9th graders ($n=86$ boys and girls). Three sets of graphs were used, each containing 24 items, presented successively in a random sequence on a computer screen: (a) pie graphs, (b) bar graphs, and (c) scatter graph. Each set comprised 6 different graphs, each presented in four different types of graphical design: a plain graph lacking any decorative elements; a graph placed on a background picture; a graph with a picture beside it; and a graph composed of illustrated specifiers. For each graph, students responded to a dual-choice question by pressing one of two assigned computer keys. Differences were found between students' response time to the different graphic types. Furthermore, for plain graphs but not for decorative ones, response time shortened as the number of data points increased. Findings suggest that decorative elements change students' focus of attention, requiring additional time for processing the perceived information. This extra time is required for distinguishing presented quantitative data from accompanying decorations. These findings bear direct implications for the design of learning materials, including, textbooks, tasks sheets, tests, and computer programs.

Graphs are powerful tools for presenting and analyzing quantitative information. As such their use and comprehension by students are extensively researched (e.g. Shah & Hoeffner, 2002). In the last few decades, due to the accessibility of graphical tools, the display of quantitative data has undergone a revolution. Pictorial elements are combined with quantitative information to create decorated graphs that are more appealing to the casual observer (Tufte, 1983). This mode of presenting quantitative information has become prevalent in mass media and textbooks. Some assume that these decorative elements enhance observer's ability to identify patterns, group visual elements into an object or a figure, and elicit semantic contexts relevant to the information presented in the graph, thus decreasing time on task. Others claim that these additions to the display divert observer's attention from the main information and increase the time required for its extraction (Kosslyn, 1994; Tufte, 1983;). Nevertheless very little research has been done on the effect of decorative elements on the interpretation and comprehension of graphs. The aim of the present study was to assess the effect of pictorial elements on the speed of students' extraction of simple data from different types of decorated graphs

Method

Participants: Eighty two students (33 boys and 49 girls) ages 14-15 participated in the study. They all learned in the ninth grade, at a private school in northern Israel. All students were of medium-class background.

Instruments and variables:

Graph types, graphic types and complexity. Three sets of graphs, each containing 24 items, were presented successively but in a random order, on a computer screen: (a) pie graphs, (b) bar graphs, and (c) scatter graph. Each set consisted of 6 graphs differing in their complexity, expressed in an increase in the number of data points. Every graph was presented in four different types of graphical design: a plain graph lacking any decorative elements; a graph placed on a background picture; a graph with a picture beside it; and a graph composed of illustrated specifiers.

Speed of data extraction. For each graph students responded to a dual-choice question, by pressing one of two assigned computer keys. Time (response time) between the appearance of each graph and the pressing of the appropriate key was measured in seconds (accuracy of ± 0.1 sec) Correct responses were distinguished from erroneous ones.

Spatial ability was assed using the following tests from the Kit of Factor-Referenced Cognitive Tests (Ekstorm, French, Harman & Dermen, 1976): The Flexibility of Closure tests (CF): hidden figures (CF-1) and hidden pattern (CF-2); and the Speed of Closure tests (CS): Gestalt completion (CS-1) and snowy pictures (CS-3).

The spatial ability tests were administered prior to the graphs task with a week interval between each test. Students were classified as having low (bottom 25% of the distribution of students' scores), average (middle 50%) and high ability score (top 25%) for each separate ability.

Findings

Average response time to data extraction questions for the full graphs set, and the total number of errors were calculated for each student.

Average response time was significantly longer for low-spatial ability students with regard to CF(1+2) tests($F(1,38)=4.745$, $p(1,43)=4.078$, $p \leq 0.05$) but not with regard to the CS-1 test ($F(1,24)=0.389$, $p>0.05$). No significant differences were found between low- and high- spatial ability groups with respect to the total number of errors. As may be expected, correlation between average response time and total number of errors show a significant increase in number of errors as the average response time decreases ($r(80) = -.315$, p

A general linear model for repeated measures was conducted to determine differences in response time with regard to within-subject variables of graph type, graphic type and complexity; and between subject variables of spatial ability: CF and CS-3. Differences were found in students' response time to the different graphic types (Pillai's Trace $F(2,77)=60.682$, $p(3,76)=5.501$, $p(5,74)=74.000$, p

Conclusions

Findings indicate that decorative elements have a certain affect on the speed of data extraction from graphs. Longer response time for extracting data from decorated graphs especially those with a picture on the side suggests that decorative elements change students' focus of attention and thus require additional time for processing the perceived information. Moreover, the decrease in time response with increase of number of data points in plain graphs may hint at students' application of Gestalt grouping processes during data extraction. The absence of the effect in the decorated graphs suggests a possible interference between decorating elements and grouping processes. Altogether, the present data may imply that excess time is needed for distinguishing presented quantitative data from accompanying decorations.

These findings bear direct implications to the design of learning materials including textbooks, tasks sheets, tests and computer programs. Students at all ages and levels of education encounter major difficulties while reading and comprehending graphs (e.g. Shah & Hoeffner, 2002;). It seems that the addition of decorative elements to the graphs would present little assistance in coping with these difficulties and could lead to their enhancement. Further research is needed to assess the possible affect of decorative elements on graph comprehension.

PAPER PRESENTATION

Educational and school effectiveness for different groups of students in China

Assessment methods, Secondary school, The role of research on learning and instruction in developing education systems

Sally Mary Thomas, University of Bristol, United Kingdom

This paper reports key findings from a UK DFID/ESRC funded study: Improving Educational Evaluation and Quality in China. In collaboration with key stakeholders (national and local policy makers, teachers, students) the study aims to develop innovation in school evaluation and guidelines for implementation to enhance school improvement efforts in mainland China. The specific focus of this paper will explore the nature and extent of educational effectiveness in mainland China, using innovative quantitative methodology (multilevel modelling) to analyse longitudinal examination, student background, school process and context data from 120+ senior secondary schools. The findings indicate significant differences in effectiveness between schools and regions in China as well as significant differential effectiveness within schools for different groups of students – a key issue related to equity. Other findings include the considerable influence of school input, process and context factors on student's attainment and progress at senior secondary school. The implications of the findings are discussed in terms of educational policy and practice in mainland China and internationally.

Introduction

This paper presents key findings from a UK Department for International Development [DFID]/Economic and Social Science Research Council [ESRC] funded study: Improving Educational Evaluation and Quality in China (IEEQC, 2010). Overall the study aims to provide quality in-depth data to enhance understanding of the complex nature of school effectiveness in China and how local context may play a key role in determining definitions of educational effectiveness & quality. Understanding education quality, learning and evaluation processes also assists in achieving

wider goals including social justice and cohesion and equal opportunities, especially for girls and disadvantaged students.

The study objectives include:

1. To identify and define the dimensions of secondary school effectiveness in China, using innovative quantitative (multilevel) techniques to create "value added" measures for different student outcomes and student groups, across three regional (west & east) LEAs, and to compare and contrast these findings to equivalent results from the UK and elsewhere.
2. To develop new theoretical insights and models of educational and school effectiveness in China that highlights the potential role and impact of different educational priorities and contexts.
3. To contribute to educational policy development (and capacity building) by providing robust and relevant new evidence, in an area where empirical data is lacking.

Theoretical framework and methods

In mainland China, raw measures of pupils' academic outcomes and entrance levels to higher education are frequently viewed as the key indicators of school quality. As a result schools with disadvantaged intakes tend to be judged unfairly, while complacency is possible amongst schools with more able pupils, and it is difficult to identify best practice. An alternative 'value added' approach aims to provide a fairer approach to accountability and evaluating school performance than the 'raw' examination results (Thomas et al, 2007). Essentially this is achieved by adjusting for students' previous attainment and other relevant factors outside the control of the school to estimate their progress, in comparison to students in other schools. The concept of value added is, therefore, both an indicator of a school's effectiveness and a tool for head teachers and their staff to use to analyse the extent to which they have effectively raised pupil achievement. Value added evaluation methods emerged from empirical studies of effective schooling that can be traced back more than 40 years and subsequently to improved statistical methodology. The latter developments involved the establishment of comprehensive and longitudinal datasets and sophisticated analysis techniques (multilevel modelling) used to create 'value added' measures of school effectiveness outlined above. The findings of school effectiveness research, largely conducted in western countries, demonstrate that schools do have a significant impact on children's attainment and progress and also that there are substantial differences between the effects of some schools (Teddlie & Reynolds, 2000). However, empirical studies of school effectiveness have only rarely been reported in mainland China, which is also notably missing from international comparative studies of school effects. Of the few limited and small-scale studies conducted to date the findings are intriguing, suggesting that senior school effects may account for up to 40 percent of the total variance in students' academic achievement and that in rural areas the equivalent figure may be higher (Peng et al, 2006, Ding & Xue 2009). Across a landscape as huge as mainland China, more large-scale and representative studies are clearly needed to provide robust quantitative evidence about the range and extent of school effectiveness in order to inform local and national policy development.

Data sources

IEEQC study 2 uses innovative quantitative methodology (multilevel modeling) to analyze the 2009 Entrance Examination to Higher Education (EEHE) examination scores, 2006 prior attainment scores and other pupil, class and school background data, collected from 97,532 students in 120+ senior secondary schools across three western and eastern LEAs in China.

Findings and Discussion

The findings from the application of a variety of different MLwin models indicate that in mainland China there are substantial and statistically significant differences between the estimates of senior secondary schools' value added effectiveness and that these differences vary across regions. Not surprisingly, across three LEAs and different subject outcomes, the percentage of total variance in student's unadjusted EEHE scores attributable to differences between schools is considerable, ranging from 20% to 40%. However, after controlling for students previous attainment on entry to senior secondary school the equivalent figures are somewhat reduced (13% to 28%). Estimates of differential school effects in terms of different academic subjects and for different student groups (eg by gender) are also reported as well as the impact of a variety of student intake, classroom, school process and contextual factors on student and school performance are examined in detail. The findings are discussed in relation to how school effectiveness, educational quality and equity may be better understood and evaluated in the Chinese context and the implications of the findings for educational quality in other international contexts.

Educational Importance of the Study Improving the quality of education and student learning is a major goal in both developed and developing countries, given the clear links drawn between better student access and outcomes and poverty reduction and stronger economic growth (EFA, 2004). In this context, school effectiveness research has

stimulated and focused educational policy makers' attention on the potential to raise overall levels of educational standards and student achievement. For example, western governments such as the UK have placed a strong focus on encouraging schools and teachers to use innovative evaluation methods and data to inform their own evaluations of the education they provide as well as to feed into accountability and inspection frameworks, and these approaches have been linked to improved student outcomes. However, there is very little comparable empirical research evidence on the range and extent of school effectiveness in mainland China and this paper aims to address this crucial gap. This evidence will inform new policy developments in mainland China; especially given the far-reaching educational reforms currently in progress (MOE, 2009). Moreover, the findings regarding school effects in China across different regions critically develops and extends the international and comparative educational effectiveness research.

PAPER PRESENTATION

Teaching for understanding: A perspective on university-students' learning for a globalized world?

Deep learning, Higher education, New Modes of Assessment

Antonia Scholkmann, Technische Universität Dortmund, Germany; Bianca Roters, Technische Universität Dortmund, Germany

When it comes to university learning, mere acquisition of declarative knowledge is no longer enough to meet the demands of a globalized world. Only if students develop skills and competencies to deal with what they have learned, teaching has reached the goals that universities stand for in Western societies. The levels of how well students are able to understand a complex scientific theory or the implications of a scientific argument might be a potent indicator for state-of-the-art university learning, as show results from an in-depth analysis of n=274 qualitative essays on the content of a scientific text. The essays were created by first-year students of Educational Psychology, taught in traditional or problem-based classes, and then classified in different levels of understanding according to a framework with references to the SOLO-taxonomy by Biggs and the taxonomy by Bloom. Results show significant variation amongst these answers, giving important hints for further discussion about the potential of the concept of understanding for teaching and testing academic success.

Introduction to Problem

The objective of student learning in higher education as a main teaching goal stands without doubt as most challenging alike: Universities and colleges are the most prominent locations for learning to take place in Western societies. But what is it that has to be learned in order to meet the demands of a globalized world, and which skills for the 'knowledge age' should universities and colleges aim to teach for?

Some evidence can be seen from research on 'state-of-the-art' teaching approaches such as problem based learning (PBL) and reflective teaching. Those approaches not only focus on fostering the acquisition of generic skills and competencies such as presenting, communication or reflecting – all of which are doubtless important domains of university learning. More importantly, these approaches claim to also enhance students' capabilities to deal with the knowledge they have acquired in a non-trivial, constructivist and even innovative way.

But what puts students in the place to apply what they have learned to new situations, problems, tasks? How can knowledge be operationalized in a cross-cultural and cross-curricular manner, so that it reflects not only declarative aspects? Which kind of testing knowledge-acquisition is appropriate and fair to students of various academic disciplines and taught by different teaching methods? And, with respect to the internalization of education: Are there certain indicators of knowledge that occur across cultural and national boundaries?

Theoretical Approaches

Our paper focuses on student learning being more than mere knowledge acquisition, but the acquisition of skills and competencies that allow dealing constructively with the specific content of a certain field or discipline. Dealing professionally with what one has learned becomes more and more superior to mere acquisition of declarative facts, as shows research on expertise (Leinhardt & Greeno, 1986; Bereiter & Scardamalia, 1993), reflection (Schön, 1983; Moore, 2004) and satisfaction and success of students (NSSE, 2010).

A concept which might help bridge all the different approaches to knowledge-related student learning is the ability to understand the content of a concept or the implications of an academic argument. We hold this idea of 'understanding' (Marton & Booth, 1997; Dahlgren, 1997) to be a central domain of university teaching. Different levels of understanding can be seen with respect to university learning, as has shown significant prior research (Wahlström et al., 1997), with some inconsistencies concerning relation to a specific teaching method (Rahimi, 1995). Given these implications the research question for this study was: Can the concept of understanding be applied as a global indicator for university learning across different countries and different teaching approaches?

Empirical Evidence

As part of a greater research project which investigates learning through different teaching methods in different universities in Sweden, the Netherlands, Switzerland and Germany, we tested for students' understanding of a complex text. By bringing together qualitative and taxonomic approaches such as Biggs' Solo-taxonomy (Biggs 2003) or the domains of Bloom (see Anderson & Krathwohl, 2001), a framework was developed to classify qualitative answers with respect to different levels of complexity in understanding.

The texts to which we will refer to in our presentation were $n = 274$ answers by first to third year students in courses of developmental psychology from Switzerland and Germany. These students were taught in either 'traditional' form or enclosing an amount of problem-based elements during the academic term. All students gave written answers to the question "What is the text about?" after reading it. Stimulus was an essay on conditions and consequences of brain development (Hyther, 2006). Tests with further groups are under way in Germany, Sweden and the Netherlands. Results from the initial sample show significant differences between the levels of understanding displayed between students in both courses (PBL vs. non-PBL), thus differentiating them in at least five groups. Amongst the answers there can be seen a pattern going from only capturing the innermost fundamental message of the text via understanding one or more than one argumentative figures given by the author, and, at the higher levels, capturing also the implication of examples and differentiating aspects to foster these arguments and connect them to an overall academic discourse.

No statistic effect could be seen for age, gender, previous studies or any predictor of academic achievement on the performance in this test, thus indicating its diagnostic uniqueness. "Missing-the-point"-answers give important hints for further theoretical refinement of the concept 'understanding'.

Implications and Relevance

The implications of this study follow a twofold way: firstly, new contributions might be inferred from the idea of 'understanding' as core concept for university learning in bringing together related concepts such as reflection, comprehension and expertise. Secondly, conceptualizing university learning from the angle of how well students are able to understand complex scientific arguments rather than simply reproducing facts allows for new ways of testing academic success, and at the same time fosters ideas of combining more alternative teaching approaches like PBL with competence-oriented testing.

PAPER PRESENTATION

Research synthesis on the effectiveness of early education programs focused on social development

Franziska Egert, German Youth Institute, Germany; Andrea G. Eckhardt, German Youth Institute, Germany

A growing body of evidence reinforces the assumption of the positive impact of early childhood education programs on the individual development of young children. While (quasi)experimental research findings clearly indicate positive effects on cognitive and academic achievement, the effects of early education programs on the social development are inconsistent, ranging from positive to negative. Therefore, the research synthesis examines to what extent center based childhood education or specialized trainings in early education programs affect the social emotional development of children birth to six years of age. To obtain eligible studies published between 1960 and 2010, electronic search in international databases and hand search in reviews and renowned journals was conducted. An extensive coding scheme was developed a) to retrieve relevant information on study design, program characteristics, structural features of center based care settings as well as child characteristics and, further, b) to cluster and characterize the studies included in the research synthesis.

The research synthesis presents eligible studies that provide sufficient findings on the impact of early childhood programs. The synthesis contributes to existing knowledge and organizes the current state of the art with an emphasis on type and quality of studies. Furthermore, it provides lineages of research from 1960 to 2010. The findings summarize the evidence of effectiveness of education programs and deduce principal contributions on structural program features for policy makers and child care providers.

Aims

Over the last decade, a number of studies had been conducted that investigate the impact of early childhood programs on child development. In general, findings indicate positive effects on cognitive and academic development. The impact of early educational programs on social development are, however, less conclusive. Results from (quasi-)experimental studies rang from positive effects to negative effects.

In order to provide a better understanding of the inconsistency, a research synthesis was conducted. The synthesis targets on (quasi-)experimental studies that assess the effects of various early childhood programs on the social

development of children birth to six years of age. It aggregates the evidence of program effectiveness of research conducted between 1960 and 2010. Focused categorization of eligible studies were used to gain a systematic overview of relevant research and to explain differential effects due to study design, program features, child care setting and child characteristics. The purpose of this presentation is a) to depict the search process and b) to present the findings of the research synthesis by characterizing eligible studies.

Methodology

The research synthesis was conducted to provide detailed information on the state of the art in the field of early childhood education program effectiveness. The methodological framework of the research synthesis consists of five major steps.

First, an electronic search in the databases ERIC, PsycINFO, Francis, BEI, AEI, ProQuest Dissertations and Theses, WISO and FIS and, in addition, a hand search of publications was conducted and approximately 3.000 citations found. Secondly, titles and abstracts of the citations found were reviewed in terms of a) having an (quasi-) experimental design, b) evaluating early education programs that target at the social development of children under 7 years, and c) using quantitative assessment instruments. In a third step, full papers of the citations were screened with a short form using 21 selective criteria. Studies had to fulfil scientific inquiries with regards to study design, assignment and matching procedure, outcome measurements, sample characteristics and program features to be included in the synthesis. Approximately 70 studies met the selective criteria. Fourth, the relevant literature was reviewed with an extensive coding scheme with 79 questions that extract more detailed information on the studies. The whole reviewing and screening process was conducted by two independent reviewers; disagreements were solved through discussion. In a fifth step, the relevant studies were analyzed and categorized with regards to information gathered in the extensive coding scheme.

Findings

The electronic search and hand search of publications resulted in 3.087 findings of relevant publication. After titles and abstracts were screened from all citations 724 publications were identified. From these approximately 70 studies met the selection criteria to be included in the research synthesis.

It has to be noticed, that quite a number of studies had to be excluded during the coding process because of missing comparison groups or insufficient information on statistical analysis. The following synthesis of study characteristics is based on the 19 results. Findings from the complete sample will be presented at the conference.

Publication characteristic: Publication years of studies relevant for the synthesis range from 1982 to 2008. However, most of the studies (70%) are published in the last 15 years. The majority of studies (80%) of the studies were conducted in North America (13 in the United States and 2 in Canada) while 20% were accomplished in Europe (3 in Germany and 1 in Sweden). About one third of the studies are characterized as unpublished (e.g., governmental reports, dissertations and thesis). The inclusion of unpublished papers is important to prevent and reduce publication bias. Because of the high ratio of unpublished papers included, screwed results caused by a lack of unpublished findings are not expected.

Study design: Most accurate estimations of the program effectiveness can be derived from random-assigned controlled experiments. Nevertheless, the current state demonstrates a lack of accurate experimental designs, because only 3 out of 19 studies used an experimental design with random assignment. All of them were conducted in the United States. Focusing on the participants, the sample size of studies included in the synthesis reach from 40 children to 3.376 children. Aggregating the data of all relevant studies, the overall sample consists of $N = 9.496$ children. Nevertheless, most of the studies (17) had child outcomes measurements at age 3 to 6, whereas only two studies offered outcome data below the age of three. Due to the lack of studies aiming at children below three years, it is not possible to synthesize general program effectiveness based on the findings of this age group.

Early education program and the child care setting: About one third of the child care programs evaluations ($N = 7$) included in the syntheses aim at children at risk, all of the programs were conducted in the United States of America. Children at risk can either be disadvantaged due to socioeconomic status of the family, migration background or due to developmental risks of the children or a combination thereof (not including children with physical or mental impairment). The other two thirds of the studies do not aim at a specific group of children. About half of the study participants are cared for in mixed age groups ($N = 9$), ranging from 0-6 years (child care centers ranging from 0-6 years or German Kindergarten ranging from 3-6 years) or homogenous groups (preschool or Pre-k serving 4 year olds and kindergarten serving 5 year old children; $N = 10$).

Theoretical and empirical significant evidence based conclusions are necessary for policy decision makers and child care providers to offer appropriate and effective services for young children. The research synthesis summarizes the evidence of effectiveness of early childhood programs by reviewing the state of the art across-the-board. Furthermore, it provides particular knowledge of structural program features that impact the level of effectiveness which lead to improved child outcomes.

PAPER PRESENTATION

Who Benefits from Meta-cognitive Instruction and Under What Conditions?

Tova Michalsky, Bar-Ilan university, Israel; Zemira Mevarech, Bar-ilan University, Israel

The purpose of the present study is twofold: (a) to examine who benefits from meta-cognitive instruction and under what conditions; and (b) to analyze the meta-cognitive processes that higher and lower achieving, activate under the different conditions. The present study is a continuation of a previous study (Author, 2007) in which we examined the differential effects of meta-cognitive support provided at different phases of elementary school students reading scientific texts: before (beMETA), during (duMETA), after (afMEA), or without meta-cognitive support (noMeta). In the present study, we focused on the differential effects of these methods on higher and lower achievers' scientific literacy, and we analyzed the meta-cognitive processes that the pupils indeed activated under the different conditions.

Theoretical Framework

The main goal of the current science education reform is the enhancement of science literacy for all students. Science literacy (SL) involves the abilities to comprehend scientific phenomena (the big ideas) and to communicate these ideas to others (PISA, 2006,). Clearly, reading scientific texts plays an essential role in enhancing science literacy, because in reading students must learn how to access, evaluate, and interpret scientific information from books, periodicals, databases, electronic communication systems, and other resources (National Research Council [NRC], 1996). It is widely believed that reading comprehension and reading strategies could be enhanced by explicit meta-cognitive instruction implemented by the regular classroom teacher (Author et al, 2005, 2007; Simonsen & Singer, 1992). Although the effects of metacognitive instruction has been documented (Author et al, 2005, 2007) many research questions are still open. In particular, who benefits from meta-cognitive instruction and under what conditions? The specific format of the meta-cognitive instruction and its potential transferability are not fully known. The purpose of the present study is threefold: (a) to examine the different conditions under which metacognitive instruction is most efficient in enhancing SL (b) to compare the effects of this conditions on higher and lower achieving students' SL; and (c) to analyze the meta-cognitive processes that higher and lower achieving students activate under the different conditions.

Research Design

Four research condition were employed: metacognitive instruction – before reading (beMETA), during reading (duMETA), or after reading (afMETA) – and a control group received none (noMETA). The metacognitive instruction was based on Mevarech and Kramarski's (1997) IMPROVE method.

Participants - Participants were 108 fourth grade pupils (mean age: 9.5 years, SD = 0.77) who studied in four heterogeneous classes, randomly selected from four Israeli elementary schools.

Data collection – All students were pre- and post-tested on Israel national, standardized test based on PISA (Organization for Economic Co-operation and Development, 2002) science literacy tests (SLT). The students were asked to 'think aloud' continuously while they were answering the pre and post tests. All 'thinking aloud' protocols were audio-taped and transcribed verbatim.

Data analysis –quantitative analyses: The SLT included 15 items: 9 open-ended questions and 6 multiple-choice items such as "What did the pupils want to research in this experiment? (a - The effects of light on the beans' seeds, b - The effects of the number of seeds on the beans' growth, c - The effects of the amount of water on the beans' growth, or d - The effects of the ground on the beans' growth). Each item was scored as either 1 (correct) or 0 (incorrect), with the total score ranging from 0-15. Inter-judge reliability, was assessed by two experts in science education, the reliability coefficients ranging from $r = .82$ to $.95$ for all skill dimensions.

Qualitative analyses- the analysis of "thinking aloud" data followed Marshall and Rossman's (1999) four stages, namely, organizing the data, generating tentative themes, testing the emergent themes, and searching for alternative explanations. In doing so, data analysis crystallized participants' metacognitive process during reading scientific text.

Results

The quantitative analysis indicates significant main effects of science literacy for both the learning conditions ($F(3,100)=6.38$, p Also the interaction between learning conditions and achieving groups was significant ($F(3,100)=15.24$, p The analyses show no significant differences between conditions for the higher achievers, whereas the lower achievers in the afMeta significantly outperformed their counterparts in the beMeta, who in turn significantly outperformed their counterparts in the duMeta, whereas the noMeta students achieved the lowest mean scores. For the lower achievers the main effect for time and the time*treatment interaction were statistically significant for all five components, $MSe = 16.21$, $F(1, 41)$, p $\eta^2 = 0.46$ and 31.25 , respectively; formulating hypotheses, 92.36 , $\eta^2 = 0.43$ and 37.12 , $\eta^2 = 0.31$, respectively; identifying dependent variables, 122.32 , $\eta^2 = 0.51$ and 43.25 , $\eta^2 = 0.35$, respectively; identifying independent variables, 146.14 , $\eta^2 = 0.57$ and 48.34 , $\eta^2 = 0.37$, respectively; and describing results and drawing conclusions, 101.21 , $\eta^2 = 0.48$ and 37.68 , $\eta^2 = 0.32$, respectively. Post hoc analyses of the lower achievers adjusted mean scores based on the pair-wise comparison t-test indicated that on the SLT all five components (describing phenomena, formulating hypotheses, identifying dependent variables, describing results and drawing conclusions), the afMETA group statistically significantly outperformed all other groups; the beMETA research group statistically significantly outperformed the duMETA group; and the noMETA group attained the lowest mean scores (all p values)

The qualitative analysis provides deeper understanding of these findings. It focuses on the meta-cognitive processes that higher and lower achievers indeed activated in the different conditions. The qualitative analyses revealed two interesting phenomena: (a) higher and lower achievers activate different kinds of meta-cognitive processes; and (b) the exposure to the different kinds of meta-cognitive support indeed resulted in the activation of different kinds of meta-cognitive processes (see table 1).

Educational Significance

The study has both theoretical and practical implications. Theoretically, the study shows how young children at the age of fourth grade pupils employ metacognitive strategies under different conditions. In addition the study indicates in what way higher achievers differ from lower achievers. Practically, the study provide evidence on efficient condition in developing SL in elementary schools.

PAPER PRESENTATION

Accuracy of Immediate and Delayed Judgments of Learning in Worked Examples and Problem Solving Tasks

Martine Baars, Erasmus University Rotterdam, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Fred Paas, Erasmus University Rotterdam, Netherlands; Anique de Bruin, Maastricht University, Netherlands

The assessment by a student of how well information is learned is called a judgment of learning (JOL). Only with an accurate JOL can a learner judge accurately what information needs to be restudied and how study time can be allocated efficiently. In Experiment 1, primary school children in grade 3 engaged in solving arithmetic problems, gave immediate or delayed JOLs and rated their invested mental effort. It was found that immediate JOLs were more accurate than delayed JOLs. Moreover, participants in the immediate JOL condition more often chose to restudy problems they did not manage to solve during the first test, suggesting more efficient study time allocation. Whether this also positively affected learning could not be established due to lack of learning gains in both conditions. In Experiment 2 it is investigated whether these findings can be replicated with secondary education students and worked examples are included to investigate effects on learning.

Research has shown that students' judgments of what information they have or have not yet learned play an important role in self-regulated learning: these judgments guide study time allocation and subsequent restudy choices (Metcalf, 2009), and as a consequence, need to be accurate to result in optimal study choices. Research on Judgments of Learning (JOLs) has mainly focused on language learning tasks (e.g., word pairs or texts; see Thiede et al., 2009). Immediate JOLs are given immediately after studying an item (e.g., text or word pair), whereas delayed JOLs are provided after studying several items. By comparing the JOLs to the performance on those items on a subsequent test, their accuracy can be measured. Research on word pairs has shown higher accuracy of delayed JOLs prompted by

the first word of the word pair (Nelson & Dunlosky, 1991). This "delayed-JOL effect" was not found, however, for learning texts with JOLs prompted by the title of the text (Maki, 1998). When providing learners with additional instructions such as to generate keywords (Thiede et al., 2005) or summarize the texts (Thiede et al., 2003), they are able to establish the accessibility of information from the text at a delay, and delayed JOLs become more accurate than immediate ones. Little is known about JOLs in the kind of procedural problem solving tasks typically seen in math and science curricula. Because self-regulated learning is also considered important in those domains, we aim to investigate JOLs in problem solving tasks. Problem solving differs from texts and word pairs in important ways. A JOL about problem solving concerns knowledge of a procedure. Learners are not supposed to judge whether they have learned the answer to this particular problem, but rather, should judge whether they know the solution procedure required for solving this type of problem.

Consequently, as with texts, only a "title", that is, a description of the problem type, is available when making a JOL. Therefore, we hypothesized that as in texts without any additional instructions, immediate JOLs would be more accurate than delayed JOLs with problem solving tasks. Experiment 1. Participants were 76 Dutch third graders who were randomly assigned to either the Immediate (N = 35) or Delayed (N = 41) JOL condition. The study was run in group sessions in classrooms (both conditions present in each session). It consisted of five phases: pretest, learning phase, first test, restudy, and second test. In the learning and test phases, the children were asked to solve four arithmetic problems, one of each of the following types: addition without carrying, addition with carrying, subtraction with borrowing tens and subtraction with borrowing tens and hundreds. During the learning phase, the children provided JOLs on a 5-point rating scale (Dunlosky & Lipko, 2007; Thiede, et al., 2003) immediately after each problem or after all four problems, depending on their assigned condition. At the end of the learning phase children could indicate which problems they would like to solve again (cf. restudy in research with texts or word pairs). Subsequently, they completed the first test, were allowed to 'restudy' problems, and completed the second test. JOL accuracy was measured by means of gamma correlations between JOLs and first test performance.

Accuracy of restudy choices was measured by comparing whether a problem was chosen for restudy or not, to performance on the first test (i.e., if a problem was not chosen for restudy, 1 point was given when it was performed correctly and 0 points when it was performed incorrectly; vice versa if a problem was chosen). A t test performed on the JOL accuracy data revealed higher accuracy in the immediate JOL condition than in the delayed JOL condition ($t(74) = 2.05$, $p = .04$, $r = .23$), which confirmed our hypothesis. For the analysis of restudy choice accuracy, data from half of the participants had to be excluded because they did not restudy only those problems they had indicated. There was a significant difference between the conditions in restudy choice accuracy, $t(36) = 2.29$, $p = .03$, $r = .36$: Children in the immediate JOL condition made more accurate choices than children in the delayed JOL condition. This higher accuracy of study choices did not lead to better learning outcomes, because no learning gains were found in either condition. Since the children in Experiment 1 were quite young (i.e. 8-10 years), the procedure of giving delayed JOLs based only on the titles of problems might have been too difficult.

To establish whether age affects the accuracy of JOLs prompted with the title of a problem, secondary school students will be involved in a second experiment on JOLs and problem solving tasks. Furthermore, to be able to investigate the effect of restudy choices on learning gains, a worked-examples condition will be added: Research on the worked-example effect has shown higher learning gains of instruction consisting of examples compared to problem solving for novices (Sweller, 2006; Paas & Van Gog, 2006). Experiment 2. Approximately 120 Dutch secondary education students will participate in this experiment. A 2x2 factorial design with factors JOL (Immediate vs. Delayed) and Problem Format (Worked Examples vs. Problems) will be used. Students will be randomly assigned to one of the four conditions. The study will be run in group sessions in classrooms (all conditions present in each session). Consistent with Experiment 1, there will be five phases: pretest, learning phase, first test, restudy, and second test. In the learning and test phases, the students will solve/study problems about electrical circuits and during the learning phase they will provide JOLs immediately after each problem or once after all problems, depending on their assigned condition. It is hypothesized that immediate JOLs will be more accurate than delayed JOLs, that students in the worked examples condition show greater learning gains, and that accuracy of restudy choices positively affects learning gains—at least in the worked examples condition. Data collection is finished in 2010 and results will be available well before the conference.

PAPER PRESENTATION

Promoting Metacognition in Industry Courses for Trainees in Lower Level VET programmes

Nadine Kipfer, IFFP, Switzerland; Ursula Scharnhorst, IFFP, Switzerland; Nicole Grolimund, Eidgenössisches Hochschulinstitut für Berufsbildung, Switzerland

Observations in industry courses with trainees in lower level vocational education and training (VET) programmes showed that they are rather passive learners. Previous research in vocational schools showed that a metacognitive training helped these trainees to become more strategic and to perform better in school tasks. The present research involves the development of a metacognitive training embedded in industry courses to support the acquisition of occupational knowledge and skills of car mechanic assistants. We expect the training to foster the apprentices' use of cognitive and metacognitive strategies in learning and problem solving. It should further enhance the trainers' efficacy in offering differentiated forms of support and guidance. Multiple research steps were conducted: (1) Field observations helped to understand the particular learning and teaching context of industry courses and to identify the occurrence of difficulties. (2) An online questionnaire was administered to assess the perception of trainers concerning trainees' cognitive and motivational learning difficulties. Trainers were also asked to describe their usual instructional approach. These first two steps allowed to identify which strategies should be trained and how their use may be fostered. (3) In collaboration with the trainers, different training components were developed, which they can integrate in their occupational-specific goals. Finally, the trainers implemented the training in their industry courses. (4) First effects have been analysed. In the paper we will present and discuss the developed metacognitive training components and first qualitative results regarding their use by the trainers.

Swiss VET programmes comprise theoretical courses at vocational school, work-based training in a host company and industry courses. The latter combine theoretical and practical aspects of VET and are also a part of the final certification. The purpose of industry courses is to instruct the competent use of machines and tools of the specific trade by teaching the trainees the corresponding knowledge and skills. Besides, soft skills (methodological, personal and social competencies) should be fostered.

Our research focuses on competencies taught in industry courses for car mechanic assistants. 'Car mechanic assistant' is one of the newly created occupational profiles in Switzerland which is trained in a two-year, lower level, VET programme.

Trainees in industry courses are often expected to solve tasks, which are organized in work stations, in an autonomous way. First observations showed that they often have difficulties to self-regulate the corresponding learning and working processes by using effective strategies to plan, monitor and control their problem solving and memorize it. In other words, they are often too passive learners.

Concerning the trainers, our observations revealed that they do not sufficiently encourage the trainees to use strategies and to develop their metacognitive awareness. Their support often focuses on the product of the tasks and not enough on the learning and problem solving processes.

A previous quasi-experimental research (Berger, Kipfer, & Býchel, 2009) showed that a metacognitive training in the vocational school setting helped the trainees to become more strategic learners and to be more aware of their own cognitive functioning in classical school tasks (e.g. mathematical and text comprehension tasks). However, it was pointed out that these positive effects may be limited and their transfer on practical problem solving contexts (e.g. at the workplace or in industry courses) was not assessed.

Considering these limitations, we adopted a design-based research approach to develop a metacognitive training in collaboration with industry course trainers so that the training components can be embedded or blended into their occupation-specific and practice-oriented training programme. The embedded metacognitive training should improve teaching and learning in industry courses: The trainees should become more strategic learners if they follow such a training. And trainers should become more competent in fostering cognitive and metacognitive strategies of their trainees besides teaching specific course contents.

Different research steps were conducted: (1) Detailed exploratory observations of teaching and learning in industry courses were undertaken. These observations were discussed with trainers to identify strengths and also major weaknesses of trainees. (2) Further, 32 trainers, who are currently teaching car mechanic assistants in industry courses, completed a questionnaire about their perceptions of the trainees' cognitive and motivational learning difficulties as well as about their own instructional approach. The results indicated which strategies should be trained and how their use may be encouraged. (3) Two working groups composed of researchers (experts of metacognitive theory and intervention) and vocational trainers (experts of occupational practice) were established. They regularly met to discuss useful and possible changes in the teaching and learning arrangement of industry courses, thus trying to adapt and enrich the trainers' instructional approach. They also developed a script for incorporating metacognitive

training components directly into the content-based, practical learning goals of the industry courses. (4) Finally, the trainers implemented these new components in their courses and the effects on teaching and learning were assessed. Multiple instruments were used to assess the effects and the practicability of this training: (A) Each trainer followed a group of trainees (approximately 10) during 8 days. (B) Each day, researchers interviewed trainers about the experiences done of the current day. (C) At the end of the 8 days, they were interviewed about their experiences in implementing the metacognitive training. (D) The trainees answered a metacognitive questionnaire before and after the 8 days of intervention. (E) The trainees were also interviewed after the solution of a specific practical task. (F) The training sessions were videotaped and coded according to an observation grid. A total of 40 apprentices from four different industry course centers participated in the study.

The paper will focus on the developed metacognitive training components and on first qualitative data concerning trainers' efficacy to implement and promote the use of metacognitive training components.

PAPER PRESENTATION

Is it helpful to force readers to search an available text? Effects of comprehension skills and JOLs

Amelia Mana, University of Valencia, Spain; Eduardo Vidal-Abarca, Universidad de Valencia, Spain

This paper examines whether forcing readers to search information in the text enhances their performance on comprehension questions. Furthermore, we are interested in study if comprehensions skills and the reader's judgments of learning (JOL) moderate that effect. To do this, we conducted an experiment in which 18 skilled and 17 less-skilled readers from 8th grade read two texts and answered eight questions per text on a computer using Read&Answer, a software tool that records the whole text-reader interaction (i.e. reading sequence). After reading each question, students rated their confidence about giving the right answer using a scale from 0 (I'm completely unsure to be able to give the right answer) to 100 (I'm completely sure to give the right answer). Students were randomly assigned to be in either the Non-Forced condition (n=18), where they were told that they were free to refer back to the text whenever they wanted, or the Forced condition (n=17), where students were required to refer back to the text in all questions. Results showed that both high and less-skilled readers in Forced condition outperformed readers in Non-Forced condition, showing a facilitative effect of forcing readers to search in both skills levels. However, this effect was different depending on the JOLs, being especially helpful for medium-level JOLs (40%-60%). On-line data of search process allows us to explain the reasons of to force to search effect

Answering questions from an available text has specific metacognitive demands due to the high level of interaction between the reader, the text and the questions, which involves monitoring and self-regulation processes (i.e. whether to search in the text or not, or what information to search). In a recent study, Vidal-Abarca, Mana, Gil & Martínez, (2009) found that readers seem to have self-regulation problems. Readers often decided not to search the text even though they were not certain to give the right answer, which seems a risky decision. The current work sought to test whether forcing readers to search the text after every question would facilitate their comprehension, and whether reading skill and their certainty of giving the right answer without re-reading the text moderates this benefit.

Comprehension monitoring has been investigated within the framework of the Judgments Of Learning (JOL) paradigm (Maki, 1998), in which students assess their level of learning or comprehension after studying some information and then they perform a learning task. JOLs predict the students' decisions to search the text, which may also explain performance (Thiede, Anderson & Theriault, 2003). In a previous study Vidal-Abarca, et al. (2009) found that high-skilled and especially less-skilled readers often decided not to search (around 50% and 70% of the time respectively) when they were not totally sure about providing the correct answer (JOLs 40-60).

Our specific interest in this study was to examine in detail the effect of forcing readers to search the text on final performance and to analyze whether comprehension skills and JOLs modulate this effect. We expected that forcing readers to search would be helpful for both less and high-skilled readers and we also expected different benefits from different JOLs.

Method

Eighteen high-skilled and seventeen less-skilled readers from 8th grade read two texts and answered eight questions per text. After reading each question, they made a JOL by responding to the following question: "How sure do you feel to give the right answer to this question without rereading the text?", though students knew they would have the text available. Students had six options from 0 (I am completely unsure to be able to give the right answer) to 100 (I am completely sure to give the right answer), using intervals of 20 units. Then, students in Forced condition had to search the text in all questions whereas students in Non-Forced condition were free to search the text at their will. Students

performed the task on a computer using software Read&Answer (Vidal-Abarca et. al, in press) which recorded readers' actions (i.e. search decisions, what information were read and the final response)

Results and discussion

As we had predicted, readers in Forced condition ($M=10.35$; $SD=2.51$) marginally outperformed readers in Non-Forced condition ($M=8.66$; $SD=2.65$), $F(1, 31)=3.923$, $p=.057$, $\eta^2_p=.11$. High-skilled readers ($M=10.55$; $SD=2.5$) also outperformed less-skilled readers ($M=8.35$; $SD=2.45$), $F(1, 31)=7.095$, $p=.019$, with no effect of interaction. Thus, we can conclude that forcing readers to search in the texts is beneficial for both less and high-skilled, because both groups improve their performance in forced condition. Our results also showed that the benefit of forcing students to search depends on the level of JOL (see fig. 1). For low-level JOLs (0-20), forcing readers to search was not helpful since the scores distribution (scores 0, 0.5 and 1) was the same in Forced condition than in Non-Forced condition for both groups ($\chi^2(2, 81)=.903$, $p=.637$; $\chi^2(2, 72)=.301$, $p=.860$, less and high-skilled respectively). For intermediate-level JOLs (40-60), forcing readers to search was helpful for both groups because they obtained significantly better scores (more scores 1 and less 0) in Forced condition than in Non-Forced condition ($\chi^2(2, 111)=9.254$, $p=.009$; $\chi^2(2, 85)=6.106$, $p=.008$; $\chi^2(2, 131)=10.691$, $p=.004$). Force condition are explained by the increase of searching opportunities, since in Non-Forced condition readers decided not to search less than 50% of the times in medium JOLs and high-skilled only 8.5% in high JOLs. Thus, forcing high-skilled readers to search is always helpful, while forcing less-skilled readers to search is only helpful in medium JOLs.

Detailed analyses of readers' behaviour when they search the text, more specifically the strategy of "using relevant information" (going directly to answer the question after reading a relevant piece of information) may explain the benefit of forcing readers to search. Forcing readers to search did not affect the frequency for readers to visit relevant information (high-skilled 74% and less-skilled 62%). However it affects the usefulness of using that information; only in Forced condition high-skilled readers, when used relevant information, obtained significantly better scores than less-skilled ($\chi^2(2, 203)=15.546$, $p=.000$).

In conclusion, forcing readers to search information in the text helps them to get better comprehension scores; however comprehension skills and JOLs modulate this effect. Forcing readers to search is helpful almost always for high-skilled readers and only helpful in intermediate-level JOLs for less-skilled readers. Furthermore, forcing high-skilled readers to search helps them to better interpret relevant information.

PAPER PRESENTATION

Enhancement of students' reading motivation and reading activity

Katrin Arens, University of Göttingen, Germany; Rainer Watermann, University of Göttingen, Germany;
Marcus Hasselhorn, DIPF, Germany

This study deals with the issue how to promote students' reading motivation after the transition from primary to secondary school with a school-based intervention. Respective interventions might have to facilitate students' needs for competence, autonomy, and relatedness as preconditions of intrinsic motivation stated by self-determination theory. However, reading motivation is shown to be primarily predicted by reading achievement. Thus, the implementation of skill development techniques fostering students' need for competence might be sufficient to promote students' reading motivation. In a pretest-posttest-follow-up design, three literacy training conditions were realized in a German secondary school attend by girls only. In order to promote students' need for competence, the teacher of one class directly taught several reading strategies. In a second class this literacy training was combined with an extended form of jigsaw, which was expected to facilitate all three needs described in the self-determination theory. A third class served as a control group. Both forms of literacy instruction were capable of increasing students' reading motivation in the short term. However, only the teacher-directed condition also showed a significant effect on reading activity. At follow-up the groups did not differ with respect to students' reading motivation and reading activity. The results hint again at the unjustified liability to overestimate the potency of cooperative learning methods

in order to foster students' motivation. In fact, the effectiveness of cooperative learning seems to depend on the concomitant learning conditions.

Due to the decrease of students' reading motivation and reading activity after the transition from primary to secondary school (e.g. Jacobs, Lanza, Osgood, Eccles & Wigfield, 2002), school-based interventions are requested to counteract this unfavourable development. However, there is still a debate on the classroom practices and instructional methods suited to foster students' reading motivation after the transition to secondary school. According to self-determination theory (Deci & Ryan, 2000) intrinsic motivation depends on the satisfaction of needs for competence, autonomy and relatedness. Consequently, learning environments facilitating these needs might enhance students' reading motivation. However, it has been shown that students' reading motivation is primarily influenced by reading achievement (McElvany, Kortenbruck & Becker, 2008). Accordingly, skill development techniques emphasising students' need for competence might be sufficient to promote students' reading motivation.

The purpose of this study was to conduct initial steps for testing which of these both approaches might be adequate to enhance students' reading motivation during the first months after the secondary school transition. As in Germany the transition to secondary school takes place after the 4th grade, 5th grade students of a girls-only school were randomly allocated to one of three literacy training conditions. These different forms of literacy training were realised by the teachers over about six weeks immediately after students' transition to secondary school. In one class the teacher directly taught five reading strategies in order to develop students' literacy skills facilitating students' need for competence in turn. In the second class ($N = 27$), this skill development technique was embedded in a learning environment prone to satisfy all three basic needs stated by self-determination theory. For this purpose the literacy training was combined with an expanded form of the cooperative learning method of jigsaw. The classical form of jigsaw was used first, since it has been empirically shown that it is suited to foster students' intrinsic motivation through its positive impact on the three basic needs described in self-determination theory (Hänze & Berger, 2007).

The classical way of jigsaw was extended twofold: To augment the probability to satisfy students' need for competence, teacher-directed lessons were included. Secondly, a practical phase was supplemented, during which students were asked to exercise the instructed reading strategies in teams. This practical phase was assumed to facilitate students' need for autonomy, competence and relatedness simultaneously. A third class served as a control group ($N = 28$), for which the reading instruction method and contents of literacy lessons were not predetermined. The students' level of intrinsic reading motivation and reading activities were assessed in a pretest-posttest-follow-up design using psychometrically sound measures of PISA 2000.

Analyses of covariance with teaching condition as between-subject factor were conducted. In order to differentiate between short-term and long-term effects two steps of analyses were conducted. First, posttest scores of reading motivation or reading activity were taken as dependent variables with pretest scores as a covariate. In the second step follow-up scores were examined controlling for pretest and posttest data. In view of the small sample size the level of significance was set at $\alpha = .10$. With posttest reading motivation as dependent variable the effect of teaching condition marginally failed to gain statistical significance ($F [2,68] = 2.24, p = .12$). Nevertheless, pairwise post-hoc analyses revealed that both forms of literacy instruction were capable of enhancing students' reading motivation in the short term with no significant difference between the two experimental conditions themselves. In the second analysis of covariance based on follow-up data there was no significant effect of teaching condition on reading motivation ($F [2, 63] = 0.25, p = .78; n.s.$). With respect to reading activity a slight superiority of the teacher-directed condition compared to the combined instruction and the control group could be shown for the short-term ($F [2, 68] = 2.41, p = .10, \text{partial } \eta^2 = .07$). Inspection of group mean levels indicated a decline of students' reading activity in the combined instruction and control group between pretest and posttest while it maintained in the teacher-directed condition. In the analysis of covariance integrating follow-up assessment no group differences in students' reading activity could be shown ($F [2, 63] = 0.71, p = .47; n.s.$).

These results indicate that at least in the short term a skill-based intervention approach facilitating students' need for competence is equally capable of promoting students' reading motivation as is an extended form of jigsaw addressing all three basic needs. Consequently, methods of cooperative learning should not be one-sidedly approved as the best way of enhancing students' motivation and these results hint again at the potency of teacher-guided learning. However, this implication must not be overgeneralized, as other cooperative learning methods than jigsaw might yield superior effects on students' intrinsic motivation and the sample of this study was restricted to German 5th grade girls. Thus, further research is still necessary in order to better understand whether there are instructional tools capable of alleviating or even stopping the decline of students' reading motivation and reading activity in the first months after the transition to secondary school.

PAPER PRESENTATION

Effects of motivation on transfer: A meta-analysis

Andreas Gegenfurtner, University of Turku, Germany

This meta-analysis (148 studies, $k = 197$, $N = 31,718$) examined effects of motivation on transfer in professional training. Based on prevailing theories in research on training motivation, the analysis included relations of transfer with motivation to learn, motivation to transfer, pre- and post-training self-efficacy, goal orientations, expectancy, and instrumentality. Results of the primary meta-analyses indicated the presence of moderator effects. Four alternative theory-driven moderator analyses tested study design artifacts with regard to instruction and knowledge type; the transfer context; time; and assessment conditions. New directions for future theory development and research are suggested, and practical implications of the findings are discussed.

1. Aims and Hypotheses

The study aimed to examine the relationship between motivation and transfer in professional training. Based on prevailing theories in training motivation research, analysis included motivation to learn, motivation to transfer, self-efficacy, goal orientations, expectancy, and instrumentality (Bandura, 1977; Dweck, 1986; Noe, 1986; Vroom, 1964). Although motivation is widely believed to be important for knowledge application and transfer (Noe, 1986; Pugh & Bergin, 2006; Renkl et al., 1996), little systematic investigations exist on the size, direction, and boundary conditions of motivation-transfer relationships. Specifically, an analysis of the boundary conditions of existing theories could contribute to future theory development. Therefore, this study also sought to identify potential moderating effects of study design artifacts. Four moderator effects were hypothesized. First, we assumed that instruction (lecture-based instruction vs. active learning; Iran-Nejad, 1990; Schwartz & Bransford, 1998) X knowledge type (declarative, procedural, self-regulatory; Schraw, 2006) would moderate motivation-transfer relationships. Second, we hypothesized that near transfer contexts would be more motivating than far transfer contexts for both social, physical, and modal dimensions (Barnett & Ceci, 2002). Third, we hypothesized that training length X measurement time would function as boundary conditions (Beier & Kanfer, 2010; Cole, 2008), with higher correlations for longer trainings and shorter time lags between the end of training and the transfer measure. Finally, we assumed that assessment criterion (transfer assessed as subsequent use, frequency of use, increased effectiveness, or correct performance) X source (self, peer, supervisor, external) would influence the size of motivation-transfer correlations, being highest for self-ratings of increased effectiveness due to the presence of self-serving bias (Mullen & Riordan, 1988).

2. Method

2.1. Database

Moderator estimation techniques available in psychometric meta-analysis seemed appropriate to address the study goal. To be included in the database, a study had to report an effect size r or other effect sizes that could be converted to r (b coefficient, t statistics, F , Z , Cohen's d). We searched the PsycINFO and Web of Science databases for the period of 1986 through 2010. We also cross-referenced previous literature reviews, and contacted researchers to send unpublished manuscripts, conference papers, or dissertations. A total of 148 articles were located and coded.

2.2. Meta-analytic procedure

We used the meta-analysis methods by Hunter and Schmidt (2004). Using full artifact distribution analysis, correlations were corrected first for sampling error and then for error of measurement. We computed population correlations, 80% credibility intervals around population correlations, and the percentage of variance explained.

2.3. Moderator analysis

Spans of the 80% credibility interval (Whitener, 1990) and the percentage of variance explained (Hunter & Schmidt, 2004) were used to detect moderator biases. Theory-driven hierarchical sub-group analyses were used to estimate confounding moderator effects.

3. Results

3.1. Study characteristics

The 148 articles reported 197 independent data sources with 376 effect sizes. Total sample size was 31,718 participants, with a mean age of 30.72 years ($SD=9.42$) and 6.88 years of work experience ($SD=6.47$). 43.62% of the participants were female ($SD=25.26$).

3.2. Estimating population correlations

Complete results of the primary meta-analyses are shown in Table 1 (appendix 1). In all motivational dimensions, the span of the 80% credibility interval and the percentage of variance explained indicated the presence of moderator effects.

3.3. Estimating moderator effects

To account for effect size heterogeneity, we conducted four theory-driven analyses of possible moderator effects.

3.3.1. Effects of instruction and knowledge type. Results indicated that, for declarative and self-regulatory knowledge, correlations between motivation and transfer tended to be higher for active learning than for lecture-based instruction. For procedural knowledge, the pattern was reversed.

3.3.2. Effects of transfer context. Results indicated higher correlations for near transfer contexts at social and modal dimensions. Contrary to our expectations, however, the pattern was reversed for the physical dimension.

3.3.3. Effects of training length and measurement time. For short trainings, correlations tended to be highest for transfer measures at immediate training end. For longer trainings, correlations were highest for measures 1 to 8 weeks post-training.

3.3.4. Effects of assessment criterion and source. Irrespective of the assessment criterion, self assessments tended to show highest motivation-transfer correlations.

4. Discussion

This meta-analysis examined the relationship between motivation and transfer in professional training. Overall, it can be concluded that motivation is an important prerequisite for knowledge application and training effectiveness (Noe, 1986; Pugh & Bergin, 2006; Renkl et al., 1996). However, the size and direction of motivation-transfer relationships was found to be moderated by study artifacts. Identification of these boundary conditions added to the understanding of motivation in professional training.

4.1. Implications for theory development

Implications for theory development are on global and local levels. On a global level, it seems that research on transfer efficiency needs to consider the profound impact of motivation that has been reiterated in this meta-analysis. Without denying the relevance of cognitive factors for transfer (Paas & Van Gog, 2008; Van Merriënboer & Sweller, 2005), motivational and affective dimensions can refine existing theory models (Schnitz et al., 2009).

On a local level, moderator analyses illustrated temporal dynamics of goal orientation. This finding is unexpected, since Dweck (1986) and others (Brett & VandeWalle, 2001) conceptualized goal orientations as stable motivational traits. This would imply a certain stability over time. Future research may further explore our meta-analytic finding of goal orientation's variance as a function of increased time lag in professional training.

4.2. Practical implications

Practical implications are significant for organizational training and for research practice. First, concerning organizational training, results indicated that traditional lecture-based trainings had high motivation-transfer relationships for procedural knowledge only; when training programs focus on declarative or self-regulatory knowledge, active learning may be more effective.

Second, concerning implications for research practice, the study identified biasing effects of study design artifacts. Decisions on assessment criteria, rating sources, and measurement times influence size and direction of motivation-transfer relationships, as does the similarity between the training and the transfer situation. Ideally, the use of longitudinal multitrait-multimethod designs may seem to help minimize the biasing effects of study artifacts, making individual research outcomes more rigorous and robust.

PAPER PRESENTATION

Relation between personal computer uses at home and achievement motivation in science

Normand Roy, University of Montreal, Canada; Roch Chouinard, University of Montreal, Canada

The aim of this study is to validate a motivational model including information and communication technology (ICT) personal uses as a predictor. Technology is now part of everyday students' life. OCDE (2006) study had shown that

90% of the students frequently use computers at home. Moreover, recent studies showed that students who use ICT at home have better grade in key subject matter (Beltran, Das et Fairlie, 2008; OCDE, 2006). To achieve the aim of this study, several auto-reported attitude scales in science and socio-demographic questions were administered to a sample of about 332 French-Canadian students (boys and girls) from five junior high-schools in grade 8th at the beginning of the school year. Cluster analyses were first conducted to create three ICT user profiles. From those profiles, achievement motivation models based on an Expectancies-values model (Chouinard, Karsenti and Roy, 2007) were tested with a multi-group structural equation. Our results showed difference between profiles. Users with various usages have higher motivation whatever uses they make of ICT. However, social-gamer users, who use ICT mostly to communicate and play games, have lower scores on motivational scales, akin to casual users. Moreover, the only negative indicator of the model is communication uses. Students in casual or social-gamer profiles who passed more time in front of a computer to communicate (chatting and emailing) also show less commitment in science. Nonetheless, teachers and parents should not think computers as a negative factor on general commitment in science, but should favour positive uses of computer at home.

Aims

Studies showed great incomes of using ICT for student in many contexts (BECTA, 2003); many variables must be studied to be able to define models and effective pedagogy with ICT. One of the key elements is to determine which factors could prevent or enable the effectiveness of the use of ICT in school. Some research groups think that the use of computers at home could greatly impact school achievement (Beltran et al., 2005; Locke and Andrews, 2004; OECD, 2003; Piette, Pons and Giroux, 2006). Studies by these groups showed emphasis on the relation between computers and grades. However, motivation could give a more global picture of the learning process and the school achievement. Researchers have showed that motivation could be linked to achievement-related behaviours, such as effort and achievement (Bandura, 1997; Pintrich & Schunk, 1996; Shernoff, Csikszentmihalyi, Schneider, & Shernoff, 2003).

Therefore, in the present study, we examine the relationship between the frequencies of use of computers at home and motivational attitudes in science.

Methodology

Participants

Data were collected in October 2005 from students who were attending five French-speaking public high schools in the Montreal area (Canada). The seven classes selected for recruitment were all regular science classes enrolled in 7th and 8th grade; all students in each classroom were asked to participate. The sample consists of 332 French-Canadian students (179 boys and 153 girls).

Procedures

The questionnaire was completed during students' science classes at the beginning of the school years. Several self-reported attitude scales from different sources were compiled into one. This questionnaire took approximately 25 minutes

Measures

Motivational scales

Six scales were used to test our achievement motivation model: Self-Efficacies in science, Mastery-Approach Goals, Performance-Approach Goals, Work-Avoidance Goals, Interest for studies in science, Commitment in science.

Self-Efficacies in science has been taken from the SMTSL Attitude Scales (Hsiao-Lin, 2005), was used to measure participants' competence beliefs ($\alpha = .72$).

Three types of goals have been measured with an instrument produced and validated by Bouffard et al. (1998). The Mastery Goals Subscale ($\alpha = .83$) entailed seven statements assessing the extent to which participants wished to master the content of their science courses. The Performance Goals Subscale ($\alpha = .68$) consisted of six statements measuring the degree to which participants set personal goals to be amongst the best in their class and to obtain high marks in science. The Avoidance Goals Subscale ($\alpha = .65$) was comprised of six statements measuring the degree to which participants set their goals to do the least possible work to pass.

To measure interest for studies in science, a new scale of six items was created ($\alpha = .88$) by the researchers.

General commitment in science represents the challenge given by a task in science. The subscale General Commitment ($\alpha = .71$) was adapted from a French version of Fennema and Sherman's (1976) Mathematics

Attitudes Scales, translated and validated by Vezeau, Chouinard, Bouffard and Couture (1998), combined with items from Hsiao-Lin and his collaborators (2005).

Items from all of these scales were rated on a six point Likert-type scale, ranging from 1 ("Strongly disagree") to 6 ("Strongly agree") for motivational scales

ICT Usages

ICT usages were measure with seven different questions about how many times students use ICT for : email, chatting, word, play games, learning programs, research for personal and research for school works. Their usage was measured with a scale ranging from 1 (Never) to 4 (Almost every days).

Data Analysis

Multi-group structural equation modeling with latent variables was performed with Amos 17.0. Profiles were composed with a two-steps cluster analysis based on ICT usages (email, chatting, word, play games, learning programs, research for personal and research for school works) performed with SPSS 18.

Findings

Clusters analysis showed three profiles. The first cluster, or multi-users, reported using all types of uses more often than other students. The second cluster, or social-gamer users, was using ICT especially to communicate and play games. The last cluster, or casual users, used ICT less often the other two profiles. Results showed some distinctions between clusters in the multi-group SEM models (multi-users/social-gamer users/casual users respectively).

Use of ICT for pedagogical applications has a positive relation with self-efficacies in science ($\beta=.24^*/.32^*/.31^*$) for all profile. Communication usage has a negative relation with interest ($\beta=.03/- .23^*/-.09$) and commitment in science ($\beta=-.06/- .20^*/.06$), only for those of the social-gamer profile. Entertainment has positive relation with self-efficacies in science ($\beta=.16/.19^*/.25^*$).

Motivation part of the model has some similarities between profiles. Self-efficacies have high positive relation ($\beta=.66^*/.62^*/.59^*$) with mastery-approach goals. Mastery and performance-approach goals have positive relation with general commitment in science ($\beta=.06/.19^*/.25^*$) and $\beta=.86^*/.86^*/.98^*$ respectively).

Two surprising results are observed. The work-avoidance goals have no direct relation with commitment in our achievement motivation model, and therefore were removed from the final model. Moreover, interest in science has little relation on both achievement goals. We observe a negative relation between interest and performance goals only for multi-users ($\beta=-.71^*$), and a relation between interest and mastery-approach goals only for social-gamer users ($\beta=.34^*$).

Significance of the research

Our research sheds new light on personal uses for computers. It seems that the type of usage, combine with the amount of time passed in front of a computer, is related to your motivation in science. Teachers and parents should not see computers as a negative influence on school performance, but should instead think to promote pedagogical use of the computer. Negative impact of computers is mostly observed in students with a limited usage of computers: social-gamer and casual users, limited to communication uses. Our hypothesis is that good and diverse use of technology allows student to develop computer skills and facilitate learning of science. However, relation between personal use and motivation is not causal. It is difficult to determine if motivation in sciences increase ICT usage or good ICT uses increase motivation. To further investigate the subject, studies designed for more in-depth exploration of computer usage at home would be required. Moreover, we should delve into the relation between computer uses, computer competencies and motivation at school.

PAPER PRESENTATION

Engineering Undergraduates' Goal Setting for Their Future and Its Motivational Implications

Wen-Ting Chung, Arizona State University, United States; Jenefer Husman, Arizona State University, United States; Jonathan Hilpert, Indiana University Purdue University Fort Wayne, United States

Undergraduate students are engaged in a learning process in which they are expected to explore, evaluate, and determine their majors, and invest time and efforts in the chosen profession in order to achieve anticipated future careers and lives. In the US, engineering, compared with other majors, has been identified as a field that students are most likely to switch to other majors or drop out. This study investigated engineering undergraduates' goal setting for their future, and its relationships with their future time perspective, perceived instrumentality of their coursework,

self-efficacy, and perceived active learning strategy use. Our results suggested that (1) engineering students set goals in many domains their future; however, only engineering-relevant professional goals (e.g., get accepted into civil engineer's corps) rather than academic goals were associated with their reported use of deep learning strategies in engineering courses; (2) engineering students who perceived more connectedness between their current course learning and their future as engineers set more professional goals relevant to engineering. Our results imply that engineering instructors might need to consider fostering students to develop their future goals beyond academic level because it is the long-term professional goals which are mostly likely to motivate students' to actively seek meanings and gain deep understanding about their course materials. In our final paper, we will also discuss the theoretical contribution regarding the relationships between Goal setting and other critical motivational variables.

Theoretical Framework

Undergraduate students are engaged in a learning process in which they are expected to explore, evaluate, and determine their majors, and invest time and efforts in the chosen profession for achieving anticipated future careers and lives. In the US, engineering has been identified as a field that students are most likely to switch to other majors or drop out. Our research team has been interested in examining how engineering students' future time perspective (FTP) could impact their classroom behaviors as well as academic and professional trajectories.

FTP theory has been growing in popularity among educational psychology researchers (Seginer, 2009). The theory suggests that individuals mentally construct episodic future paths which guide and dictate present behaviors and decision making (Husman & Shell, 2008; Nurmi, 2005; Zimbardo & Boyd, 1999). However, there is little research designed to examine what the content of students' mental representations of the future looks like and its impacts on students' academic and professional paths. This study primarily investigated engineering undergraduates' goal setting, and its relationships with other critical motivational variables.

Research hypotheses: (1) Students who perceived more connectedness between their current learning and engineering future would report more academic and professional goals relevant to engineering. (2) Students who reported more academic or professional goals relevant to engineering would also reported that they (a) engaged more in using deep learning strategy, (b) had higher confidence to succeed in engineering courses, and (c) perceived their current learning in engineering courses was more useful for their future; (3) Students' goal setting partially mediated the relationships between connectedness to engineering and deep learning strategy use as well as perceived instrumentality.

Methods

Participants

Participants (N=366) were recruited in a large sample of post-secondary mechanical and aerospace engineering students from a variety of undergraduate courses.

Open Ended Measures

Future Goals – Participants were asked to describe ten important future goals and list the age at which they would like to achieve those goals. We coded their personal goals using an emergent approach; six categories emerged: Academic, Professional, Monetary, Domestic, Community Building, and Personal. For the purposes of this study, we focused on professional and academic goals relevant to engineering. An Academic goal would be “to graduate”; an Engineering Academic goal would be “to graduate as an engineer.”

Survey Measures

Connectedness to Engineering– measured using an adapted version of the connectedness subscale of the FTPS (Husman & Shell, 2008). Example items: “One should be taking steps today to help realize future engineering goals.”

Perceived Instrumentality (PI) – measured using the endogenous subscale of the Perceived Instrumentality Scale (Husman et al, 2004). Example items: “I will use the information I learn in [Engineering Course] in other classes I will take in the future,”

Deep learning strategy use – measured using the knowledge building subscale of the Student Perceptions of Classroom Knowledge Building Scale (SPOCK) (Shell, et al., 2005). Example items: “In [Engineering Course], I focus on developing my own understanding of the important ideas in what I am studying or reading.”

Self-efficacy – measured using Motivational Strategies for Learning Questionnaire (MSLQ) (Pintrich et al, 1993). Example items: “I am confident I can do an excellent job on the assignments and tests in this course.”

Analysis and Results

Hypothesis 1

Bivariate correlations were conducted between Connectedness-to-Engineering and the number of Goals, either Academic (not significantly correlated, $r < .01$) or Professional (weakly significantly positively correlated, $r = .14$). To further examine whether engineering-relevant goals were correlated with Connectedness-to-Engineering, engineering relevant and non-engineering goals were separated within either professional or academic goals.

Non-engineering goals (either academic or professional) are normally distributed, but engineering relevant goals (either academic or professional) were positively skewed. Approximately half of the student did not report explicit engineering goals. For both Academic and Professional goals, students' were split into two groups: Students who reported ANY or NO engineering related goals.

Bivariate correlations were first conducted between Connectedness-to-Engineering and non-engineering goals. As expected, the results were not significantly (non-engineering academic: $r = -.05$; non-engineering professional, $r = .04$). To determine if students who reported engineering goals also reported significantly higher Connectedness- to-Engineering, two t-tests were conducted. Students who reported engineering academic goals were not significantly different from those that did not. Students who had Engineering Professional Goals reported significantly higher Connectedness-to-Engineering, $t(364) = -3.02$, $p < .01$.

Hypothesis 2

To determine if there is a relationship between students reporting of an engineering Academic or Professional goal and the variables of interests, a series of t-tests were conducted: (1) Engineering Academic Goal: the results were significant for Self-efficacy, $t(364) = -2.06$, $p < .05$, and PI, $t(364) = -3.29$, $p < .01$; (2) Engineering Professional Goal: the results were significant for deep learning strategy use, $t(364) = -2.69$, $p < .01$, and PI, $t(364) = -2.17$, $p < .05$.

Hypothesis 3

Bivariate correlational analysis between Connectedness-to-Engineering and students' reported strategy use and their motivational beliefs replicated previous research. Reported learning strategy use ($r = .24$), and PI ($r = .30$) are significantly related to Connectedness-to-Engineering.

These findings indicate that students who are Connected to their future as engineers are more likely to have professional engineering goals as well as to use deep learning strategies and perceive engineering courses as instrumental. We further examine the potential of students' future professional goals to partially mediate the relationship between students Connectedness- to-Engineering and their motivational beliefs and approaches to learning.

When split into two groups, the relationship of PI to their Connectedness-to-Engineering is lower for students who reported engineering professional goals ($r = .15$, $p = .06$); who do not report ($r = .29$, $p < .01$). The relationship of deep learning strategy use and their Connectedness-to-Engineering is lower for students who reported engineering professional goals ($r = .17$, $p < .05$); who do not report ($r = .38$, $p < .01$).

Significance

Our results imply that engineering instructors might need to consider helping develop students' future goals beyond academic level because it is the long-term professional goals which motivate students to actively seek meanings and gain deep understanding about their course materials. Our final paper will also discuss the theoretical contribution regarding the role of Goal setting and its relationships to other motivational constructs.

PAPER PRESENTATION

Research Ethics Education: a descriptive map

Valentina Mazzoni, University of Verona, Italy; Luigina Mortari, University of Verona, Italy

When we have decided to realize a study on Ethic education we developed a literature review, in order to know the different perspectives using by the researchers in this field. Because of the great number of empirical approaches developed in the research practices and the different themes faced by the researchers in any topic we have decided to conduct a systematic review.

Systematic Review is used in order to determinate what is know and what is not know about a topic of interest, reflect on the processes and perspectives of the relevant body of research, explore the underlying methodological decisions and theoretical influences and suggest future directions for researchers (Paterson & Thorne, 2003).

The aim of our systematic review is to know the current research landscape about ethic education. What kinds of researches are realized? Which are the theoretical frameworks the researchers take into account in developing their works? What are the predominant methods used?

The objective of the inquiry is to delineate a descriptive map of the studies in order to define ethic education from the ground-up that is describing ethic education as it is developed in the research practice.

The finding of the systematic review will be a descriptive map, which give to researchers a tool to clarify the "state of the art" on researches in ethic education and to discuss where placing ourselves as researchers in this field.

The research

This study is part of a complex theoretical and empirical research on ethic education with primary school's children. Two main focuses compose the research: a theoretical focus and an empirical one.

The theoretical focus aims to develop a theory of Ethics education grounded in the ancient Greek philosophy, with particular attention to the Aristotle's idea of Ethics and in the current Gilligan's perspective on the ethic of care. The empirical study is oriented to realize a research with children on virtues, in order to outline which kind of education enables children to develop an ethical disposition to virtues.

In order to develop this research project, from both the theoretical and the empirical side, one of the main aspects is to place our work in the current paramount of researches on this topic. From the theoretical perspective, we choose to place the project in the Virtue Ethics approach. From the empirical perspective the choice was more difficult, because of the great number of empirical approaches used in the research practices and the different topics faced by the researchers.

In order to place our study in the present research's landscape we decided to develop a literature review to know the different perspectives using in ethic education's research projects. The recent increase of sources in delivering primary studies changes the way in which researchers realize literature review on a particular topic and systematic reviews (both meta-analysis and meta-synthesis) become the new methods to reviewing the studies (evaluating and interpreting them) in order to synthesize the scientific literature.

Aim

Systematic Review (Meta-Synthesis) is used in order to determinate what is know and what is not know about a topic of interest, reflect on the processes and perspectives of the relevant body of research, explore the underlying methodological decisions and theoretical influences and suggest future directions for researchers (Paterson & Thorne, 2003).

The aim of the systematic review we have conducted is to know the current research landscape about ethic education. What kinds of researches are realized? Which are the theoretical frameworks the researchers take into account in developing their works? What are the predominant methods used?

The objective of the inquiry is to delineate a descriptive map of the studies in order to define ethic education from the ground-up that is describing ethic education as it is developed in the research practice.

Methodology

The review is conducted on primary studies, which were collected searching through Electronic databases - three databases were included in the study: ERIC, A+Education and ERC – and the research was conducted combining thesaurus's criteria - the different –subjects» that concern the moral education's category – and time's criteria – the last 5 years. The discussion of the criteria adopted is part of the presentation.

The analysis process of the articles aims to interpret and synthesize the findings in order to realized a theoretical description (comprehensive and thickly), which is useful to explain theories, methods and models used in ethic education's studies.

Findings

The result of this systematic review on the research in ethic education is a descriptive map, which outlines:

- the different perspectives in ethic education;
- a list of key words, which give an idea about what are the concepts that perform ethic education in the researches practice;
- a list of topics that concern the ethic education today.

Significance

The great number of projects in ethic education gives new efforts to the researchers in this field as well as increases the complexity of the research landscape. Which is the –quality» of these studies?

In order to answer this prime question it's firstly necessary to design a descriptive map, which gives to the researchers a paramount of what is the idea of ethic education in the research practice (i.e. approaches, methodologies and methods). The finding of the systematic review will be a descriptive map, which give to researchers a tool to clarify the "state of the art" on researches in ethic education and to discuss where placing ourselves as researchers in this field.

PAPER PRESENTATION

Figures' value and place - a learning study on arithmetic in grade seven

Mona Holmqvist, University of Gothenborg, Sweden

This study aims to describe in what way pupils in grade seven experience the base 10 positional numeration system (place-value system) before and after three different designed lessons in a learning study, each one given to one group of students (A, B and C). By analyzing the three video-recorded research lessons differences in the students' ways of developing knowledge can be answered by what actually happened in the class room. The model used in this study is learning study with three different designed research lessons, one per students group, where the results of the former is due to the developed design of the later. The design of the research lessons are based on variation theory. In total 52 students participated in three different groups (A=13, B=19, C=20) together with their five teachers and one researcher. A test was taken by the students before and after the research lesson, which included 8 questions and 5 of those have sub queries, which resulted in 23 as a total score. A delayed post-test was given the students four weeks after the research lessons. The results from the pre- and post-test show a change in learning outcome which varies in the different groups of students (A +4, B +1, C +14).. In lesson C at least one critical aspect, namely the difference between ten and tenth, hundred and hundredth, and so on this was offered the students to discern which was not offered in the other two lessons in the same distinct way.

Aim

This study aims to describe in what way pupils in grade seven experience the base 10 positional numeration system (place-value system) before and after three different designed lessons in a learning study, each one given to one group of students (A, B and C). By analyzing the three video-recorded research lessons differences in the students' ways of developing knowledge can be answered by what actually happened in the class room. When the students solve two different kinds of arithmetical tasks; how to use decimal terms in addition and decimal factors in multiplication, their knowledge on the base 10 positional system are crucial. One hypothesis is that the different ways of solving the two tasks, in which one requires knowledge about place-value, affect their possibilities in different ways. The multiplication $0.5 * 0.5$ does not require knowledge about the base 10 positional numeration system as it is possible to count the amount of decimals in the factors (two) and by that put the dot two steps to the left (0.25). But the addition of the terms 0.2 and 0.22 is difficult to solve without knowledge about the base 10 positional numeration system. Otherwise it is easy to get the sum 0.24 instead of 0.42.

Methodology

The model used in this study is learning study (Marton & Tsui, 2004) with three different designed research lessons, one per students group, where the results of the former is due to the developed design of the later. The design of the research lessons are based on variation theory (Marton & Booth, 1997), which means critical aspects of the object of learning are offered the students in different ways. This variation of in what way the features are offered gives the students different ways to experience and by that learn. In total 52 students participated in three different groups (A=13, B=19, C=20) together with their five teachers and one researcher. The learning study started with two meetings with the teachers to present the theory which the study is based, variation theory, and to plan tests and lessons. The test was given to another class to see if the questions were suitable and the time it takes to answer the questions were reasonable (10-15 minutes). The test included 8 questions and 5 of those have sub queries, which resulted in 23 as a total score. The test was taken before and after the research lesson in each group, and a delayed post-test was given the students four weeks after the research lessons.

Findings

The results from the pre- and post-test show a change in learning outcome which varies in the different groups of students. In group A, 27% of the answers were correct in the pre-test and 31% in the post-test (+4). Group B showed the less improvement – from 51% in the pre-test to 52% in the post-test (+1). Finally, in group C the results increased from 50% to 64% (+14). This was due to the finding of at least one critical aspect, namely the difference between ten and one tenth, hundred and hundredth, and so on. In lesson C this was offered the students to discern which was not offered in the other two lessons in the same distinct way. The results also show in what way the students' abilities to solve the addition and multiplication tasks develop.

Theoretical and Educational significance of the research

In previous studies, children's difficulties with base ten numeration was studied in a teacher training course (Sawada & Atkinson, 1981). The results in a study of 106 students shows that work with a nondecimal numeration system including new number symbols and names can lead to heightened awareness and appreciation of difficulties that children might have in understanding base ten numeration. In another study, preservice teachers' knowledge of decimal numeration was tested (Stacey, Steinle, Baturo, Irwin & Bana, 2001). The results showed that pre-service teachers had inadequate content knowledge of decimals and were confused about the size of decimals in relation to zero. The results of the study described in this abstract shows both how the aspects critical for learning are possible to find by examining the students' learning outcome in relation to what happens in the research lessons. It seems as the knowledge on the base 10 positional numeration system, or lack of such knowledge, are important not only to solve additions and multiplications correct, but also to understand why a multiplication with decimals ends up in a product smaller than the factors; $0.5 * 0.5 = 0.25$. If the students understand the base 10 positional numeration system and the difference between the left and right side (ten and one tenth), they might understand multiplication of decimals as a division as the term is divided several times in smaller parts. The lack of an overall comprehension seems to make it difficult even for students at later levels of the educational system, and as pre-service teachers also seem to lack this kind of knowledge it is an area important to study.

PAPER PRESENTATION

Conjoint analysis as an instrument to measure student perceptions of education quality

Margriet van der Sluis, Maastricht University, Netherlands

In this paper we apply conjoint analysis to measure students perceptions. Conjoint requires respondents to simultaneously evaluate aspects following trade offs and is therefore seen as more realistic than traditional survey methods. Our students repeatedly ranked descriptions of 4 courses, existing of 9 quality aspects with varying scores. Subsequently, the students completed a traditional survey with statements on several aspects of educational quality, including the 9 aspects used in the conjoint task. 334 students of administrative, social pedagogical and building studies, aged 17-19, participated in the study. The scores of the conjoint task, indicating the relative importance of aspects, appear to yield a different insight in the ideas of students towards aspects of education quality than the survey questions. Some aspects with high average scores in the survey, lost significance in the conjoint task, whereas other aspects gained significance. By systematically comparing both methods on subgroups we further explore the differences and argue that conjoint is a valuable addition to traditional surveys in educational research.

Conjoint analysis as an instrument to measure student perceptions of education quality AimsFor school administrators, teachers, policy analysts and educational researchers, it is important to know how students value different aspects of educational quality and what they find important. Especially in secondary and higher (vocational) education, student evaluations are used more and more to shape or improve the educational practice. Often, however, students' opinions are measured with traditional surveys, in which aspects of quality are assessed independent of each other. Shaping the educational practice though, is in fact full of trade-offs. There is a limited budget, and there are choices to be made in which part of the educational process the investment is most worthwhile. Conjoint analysis uses the principle of trade-off and might therefore do more justice to reality. This article explores the use of conjoint analysis in the field of educational quality. The aim is to find out what students find important when being forced to make choices, and to compare this with how they evaluate the same aspects in a traditional survey. MethodologyOur study uses conjoint analysis (Batsell & Louviere, 1991; Leslie & Ettenson, 2000; Neil, 1992; Jeffries & Maeder, 2005; de Wolf, 2000). In a conjoint study, a hypothetical product or service is defined in terms of a few important characteristics. Instead of valuing the characteristics separately, the respondent simultaneously evaluates and combines the information on multiple product-service characteristics.

The objective of conjoint analysis is to determine what combination of a limited number of indicators is most influential on respondent choice or decision-making. We chose to include 9 characteristics in the study. In a pre-study among students this number turned out to be manageable. We wanted the 9 characteristics to fulfill three requirements. Firstly, three in a pre-study described perspectives are reflected in the characteristics: the labor market perspective, the educational effectiveness perspective and the social economic perspective. Secondly, the set of characteristics encompasses both process and product aspects of education. And finally, each characteristic plays a significant role in the present-day Dutch Vocational Education and Training (VET) sector. We assigned two or three possible values to each character. Participants were shown four sets of four profiles on the computer. The values were assigned to the profiles according to pre-set rules, which maximized variation in each set. Figure 1 shows an example of the profiles the participants saw on their computer screen. The question above is "Which course matches most with your idea of quality? Rank the courses according to your preferences". On the left the nine characteristics are shown. The respondents had to rank the vocational courses using the bottom four blocks with the options from 1 (the best) to 4 (the worst). Figure 1. Example of 4 profiles the participants faced on the screen.[In appendix]

To identify the impact the course characteristics on the choices of students in the conjoint task we used rank ordered logistic regression. This model interprets the 4x4 rankings assigned to the courses by our respondents as a rank ordering of choices out of a given choice set. After the conjoint task, students had to value quality aspects on a 10 point scale, in which 5 indicated 'I find this very important', 0 'neutral', and -5 'I'd rather not have this'. In the survey 37 aspects were valued, including the nine aspects that were selected for the conjoint task. Findings In the study 334 students from administrative studies, building and construction studies, and social pedagogic studies were surveyed. They completed the survey in the classroom. 56% of the students were male. The results of the both the survey and the conjoint task are seen in table 1. In the survey, teacher quality and diploma result scored highest, with a mean score of 4,05 and 3,89. The second column represents the outcomes of the conjoint task. The coefficients indicate the weight that the four participants groups placed on each of the nine quality aspects when ranking the courses.

In the conjoint task diploma result was the most important characteristic (.25) directly followed by structure (.24). Schooling hours and guiding hours in workplace learning were of minor importance for the students. The three aspects with the highest scores in the survey, teacher quality, diploma result and employers' satisfaction, are also highly valued (over .20) in the conjoint task. Furthermore, schooling hours appeared to be the least important aspect for the students in both the survey and the conjoint task. There are, however, some striking differences between both outcomes. Civic education, that scored only 0,43 in the survey, appeared to have substantial influence on the choices made in the conjoint task (.19). For the aspect guidance in workplace learning it is the other way around; it had a high average score in the survey (3,73), whereas in the conjoint task it is completely overruled by the other aspects (.03). Figure 1 shows the differences between both methods in a bar chart. Figure 2. Bar Chart. The importance of nine course characteristics according to the students in a survey compared to a conjoint task. [In Appendix] In the final paper we will further explore the differences between both methods. We will compare the results of subgroups (divided according to gender, age, study field, personality traits) on both methods.

Theoretical & educational significance 1.

This study shows how conjoint can be applied to the subject of educational quality. It explains the different steps of the conjoint study: the selection of aspects, the number of aspects and vignettes, the (digital) programming of the study and the analyzing of the outcomes. 2. Conjoint analysis is a relatively new way to examine perceptions of education quality. This study shows the differences of the conjoint analyses with the more traditional survey.

PAPER PRESENTATION

A new approach to 'text quality'

Victoria Johansson, Lund University, Sweden; Asa Wengelin, Lund University, Sweden; Roger Johansson, Lund University, Sweden

This paper is an approach to discuss the complicated measure of text quality – what do we mean by it, and what to we measure? We present a method for training reviewers to evaluate texts, and we investigate the text quality in a data set consisting of 84 expository texts, produced in ScriptLog, by four groups: 1. University students without reading and writing difficulties (RWD), 2. University students with RWD, 3. 15-year-olds without RWD, 4. 15-year-olds with RWD.

After a training process involving both holistic and analytic methods, the reviewers evaluated the data set with unusually high interreliability (Cronbach's alpha = .917). Not surprisingly, the texts by the adults without RWD were ranked the highest, followed by adults with RWD, 15-year-olds without RWD and 15-year-olds with RWD.

Further, we compared the text quality between adults and 15-year-olds without RWD, using writing speed and text length as co-variables. The results show that the quality evaluations are not dependent on either. This opens up for some new interpretations, since text quality has usually correlated with text length.

It is important that teachers or researchers, using increased text quality as evidence for development of any kind define what is meant by this notion.

In writing research, the importance of various writing process, as well as the written product is often related to text quality. Typically, text quality is related to various sets of text characteristics, e.g. text length, production rate, lexical measures, or the writer's age or schooling, and often increased text quality is seen as an important outcome of e.g. an intervention (cf. e.g. Rijlaarsdam et al, 2008). However, it is not always discussed what is meant by text quality, or how it is measured.

This paper is an approach a) to discuss the complicated measure of text quality, b) to present a method for training reviewers to evaluate texts, and c) to investigate the text quality in a data set consisting of 84 expository texts, produced using a keystroke-logging program (ScriptLog) by four different groups: 1. University students without any reading and writing difficulties (RWD), 2. University students with RWD, 3. 15-year-olds without any RWD, 4. 15-year-olds with RWD.

We engaged three reviewers (with a background including at least a master exam with linguistics; only one of them had worked as a teacher). Their task was to agree on a scale to use for judging text quality, and thereafter to identify properties, characteristic for each grade in the scale. Prior to the evaluation of the data set in our investigation, the three reviewers were trained on several sets of texts of the same type (e.g. expositorys) written by different age-groups (ranging from age 13 to adult university students; however no texts in the training data were produced by persons with RWD). In the first stage, their task was to evaluate texts on holistic grounds. The second stage was to group the rated texts, and agree on a scale to use, based on the grouping of the text. This led to a four-grade scale. The third stage was then to agree on text properties typical for each grade, and to select one or two model texts from each grade. The fourth stage was to train on a set of texts grading them using the model texts and the criteria for each text. In the fifth, and final stage, they graded the data set that we investigate in this study. The reliability between the reviewers proved to be high (Cronbach's $\alpha = .917$). This is notable, since e.g. Lofqvist (1990) report that a correlation around .70 will be considered a high agreement between teachers' judgements of student papers. The high interreliability in our study is thus a sign of that the method of working with both holistic and analytic methods to rate text quality can increase the certainty of how texts are evaluated.

When we relate the quality ratings to the four groups of writers in the data set we were interested in, we find that the texts written by the adults without RWD have the highest quality, followed by the adults with RWD. Thereafter follow the 15-year-olds without RWD and the group with the lowest quality is the 15-year-olds with RWD. This is not an unexpected result, considering the age differences between the groups, and the difficulties with text production that are typical for the groups with reading and writing difficulties. The question is whether this approach to measure text quality would have been the same if we e.g. had compared groups that were more similar in age, education or writing ability. Another question is whether the use of a more fine-graded scale would have led to a different grading.

Further, we compared the text quality between adults and 15-year-olds without RWD, using writing speed (e.g. median transitions between keystrokes within a word) and text length (e.g. number of keystrokes in the final texts) as co-variables. The results show that the quality evaluations are not dependent on text length or writing speed. This opens up for some new interpretations, since we know from other studies (e.g. Grandin & Lindskog) that text length (and thus also the ability to produce much text fast) is usually strongly correlated with text quality.

It is important to continue to discuss the notion of text quality, what is meant by it, and what contributes to an increased quality, in the light of recent changes in the educational system. For instance, in Swedish schools, a new set of additional national testing is proposed. How could children's writing development be discussed and judged if there are no reliable methods of measuring text quality? If 'text quality' is used for proving the developmental outcome in any way, it is finally of equal importance for every researcher who uses the notion of text quality to clarify exactly what is meant by it.

PAPER PRESENTATION

Predicting Adolescent Truancy – Individual Judgments and Classroom Factors

Christine Saelzer, Education (IfE), Germany

Only little is known about the association of classroom characteristics with adolescent truancy. An unresolved critical question is whether high achievement standards, high workload, and high pace do protect against or increase adolescent truancy. In this study, self-reports from 3,500 Swiss middle and high school students in 202 classes (in 28 schools) were used to predict truancy. The multilevel latent covariate approach (MLC) implemented in Mplus was implemented to specify hierarchical models. These models served to differentiate between the student and the classroom level. It was found that high achievement standards were associated with a lower truancy rate at both the student and the classroom level, whereas a high pace during lessons was associated with more truancy. At the student level, the perception of low workload was an additional predictor of high truancy.

Predicting Adolescent Truancy –

Individual Judgments and Classroom Factors Research Topics and Objectives

Truancy is known to be an important predictor of premature school dropout (Rumberger, 2000). Skipping lessons is seen mainly as an individual student's behavior within an institutional context (Claes, Hooghe & Reeskens, 2009; Rothman, 2001). Focusing at the individual level, students who truant are often thought of as being academically weak and over-challenged at school (Fogelman, Tibbenham & Lambert, 1980; Tyerman, 1986). On the other hand, there is a reasonable argument that truancy may also be linked to high academic potential (Rumberger, 1987; Voss, 1966).

According to Walberg and Ahlgren (1970), learning outcomes represent a function of three distinct construct domains including aptitudinal variables, instructional variables, and environmental variables. Key to this claim is that environmental variables explain variance in learning outcomes over and above the amount of variance explained by instructional and ability variables. This paper applies Walberg and Ahlgren's theory to truancy and thus bridges a gap in truancy research by taking into account two aspects: (a) classrooms as learning contexts and (b) predictors of truancy. The focus is given to students' workload, pressure to perform, and pace during lessons. Two research questions are focused on: How can individual characteristics explain truant behavior? And how are classroom characteristics related to truancy?

Data and MethodsSample

Participants consisted of a total of 3491 Swiss seventh to ninth graders ($n = 1142$ grade 7, $n = 1314$ grade 8, $n = 1089$ grade 9) in 202 classes in 28 schools and their teachers and principals.

Instruments

Truancy was measured by a weighted frequency index consisting of seven items which focus on skipping single lessons, half and whole school days as well as several days in a row. Students' background factors were collected including gender, grade level, grades, class repetition, nationality, school level, and SES ([HISEI]) as well as individual and family-related scales. School characteristics were measured using structural criteria (e.g. school size, geographic situation) and students' and teachers' opinions concerning processes and classroom climate issues. Most of the scales were adapted from Eder's (1998) school study.

Analyses

For this analysis, the multilevel latent covariate approach (MLC) implemented in Mplus was adopted, which takes the unreliability of the group mean into account when estimating the contextual effect. The group average is thus treated as a latent variable. A nested multilevel model was specified using Mplus 5.2 (Muth  n & Muth  n, 1998-2007) in order to predict truancy from individual covariates, individual student judgments and aggregated class level (latent) covariates.

Results and Conclusions

Table 1

Most strikingly, in model 3, both pressure to perform and pace during lessons were significant predictors of truancy ($b = -.09$; $b = .12$) at the individual level and were associated with truant behavior when used as latent covariates at the class level (pressure to perform: $b = -.28$; pace during lessons: $b = .25$). Explained variance was low at the individual level (6%) and intermediate at the class level (35%). It was thus verified that shared classroom perceptions mattered for a student's decision to play truant.

Educational and Scientific Importance of the Study

Truancy is still seen as a minor problem by teachers and principals, but it is likely to become a major social problem during the next few years. The importance of truancy as a step towards school dropout is of immense social

importance given the costs of students disconnecting themselves from the educational process. Understanding how truancy is related to classroom characteristics and how individuals respond to these features is useful in finding effective levers to prevent and deal with truancy as an unwanted student behavioral pattern. The level of perceived challenge is, both at the individual and the contextual level, a possible lever to prevent truancy.

PAPER PRESENTATION

Schooling and students' well being: a review of qualitative studies

Mara Westling Allodi, Stockholm University, Sweden

A systematic literature review of qualitative studies on the experiences and perceptions of school of Swedish children and adolescents was performed after literature searches in international and national databases. A narrative synthesis of 38 studies is presented focusing on the relationship between schooling and students' well being and mental health. Four themes were identified: general experiences (emotions, self-concept, choices); protective experiences (activities, participation, supportive relationships), risk experiences (tests, stress, school failure, negative evaluations, learning difficulties, lack of interest, negative relationships with teachers and peers); specific individual risks (disability, stigma, family problems, abuse, addiction, body image). The results are discussed in relation to developmental theories, special educational practices and current evaluation practices. The methodology of systematic review of qualitative studies applied in the field of educational research is discussed.

People's experiences and perceptions that are collected with non-experimental and qualitative studies can make a valuable contribution to an understanding of the meanings of processes and of relationships between phenomena. The object of this study was the relationships between educational experiences and students' well being and mental health. The methodologies of systematic review of qualitative research have been applied to a review of qualitative studies on Swedish children and adolescent's experiences of mental health and well being at school. The review was conducted as a part of a systematic review of research on "School, learning and mental health" performed by appointment of the Swedish Royal Academy of Sciences. The motives for doing a review of studies reporting children's and adolescents views on these matters was the ethical consideration to consider children and adolescents as subjects, having a right to express their views in matters that affect them; and the need to take account of the specific Swedish social and educational context through the experiences of the students that actively take part of it.

The aim of the review was to gather testimonies that can give indications of the experiences of mental health and well being of students in the Swedish educational system. Literature searches in several research databases with international and national publications were performed during spring 2009. A systematic screening of titles and abstracts was done on 527 references; 107 references were then screened in full text and 38 reports were judged to meet the inclusion criteria, requiring the presence of reports of children or adolescents' views, and that both aspects of mental health and of educational factors were treated in the study. The studies included were written by authors from fifteen Universities; they consisted of doctoral dissertations, academic papers, peer-reviewed articles and reports from agencies and organisation, representing the disciplines of science of education, disability studies, psychology, public health, youth studies, social work and interdisciplinary. The studies included in the review collected the students' views by mean of individual interviews, focus group interviews, observations, texts, phone conversations, internet messages, surveys and drawings. The results from the studies that were relevant for the aims of the review are structured in four themes: general views (well being, emotions, self-concept, stress, choices); protective experiences (activities, achievement, enjoyment, mastery, relationships, participation); risk situations (tests, school failure, academic expectations, lack of meaning, lack of adaptation, conformism, alienation,

relationships, victimization, exclusion); individual risk (disability, special educational settings, stigma, family problems, abuse, addiction, mental illness, body image).

The results are presented in a narrative synthesis, giving a particular weight to the direct and indirect report of children's and adolescents' own views. The theme general views is represented by six studies. The adolescents defined mental health as emotional experiences, seen both as internal feelings and as relational feelings. Family, friends and educational environments as social and physical environments were perceived as determinants of mental health. A great number of feelings were related to school. The students expressed what characterize a healthy school environment and also that harassment and rejection at school, performance stress, worries about grades and future prospects could be threats against self-worth and self-esteem, while teachers that do not care could generate negative experiences. Various kind of stress could be described and various strategies to resist stressful situations: for instance emotional support, safety and involvement.

The educational environments can be an arena for social, cognitive and emotional experiences, relationships and accomplishments that are enriching the individuals and increase their well being. General structural characteristics of the educational environments may also affect well being in different directions: performance, evaluation and feedback, freedom of choice and responsibility for the future may be perceived as a burden. The protective experiences were described in nine studies that emphasised the protective role of supporting relationships with teachers and friends. Caring relationships with the teacher involve their instructional skills, their beliefs in the students' potentials, and their firmness in keeping helping the students, never giving up their efforts.

The relationships with peers are important for the students' well being and even for their commitment to school work. A relationship with caring staff at school could be a decisive turning point for students with family troubles. Success and mastery experienced at school can make the students feel empowered and more competent. The learning environment could be also experienced as a healthy heaven, a safe place filled with activities, that make you feel purposeful and engaged. Risk experiences in school was the fourth theme, represented by 25 studies. School difficulties and special educational interventions could be perceived as stigmatizing and contributing to embarrassment, lowered status or simply to an undesired separation from the company of peers, and sometimes also to harassments.

The competition, the pressure to get good grades experienced in certain groups could cause performance anxiety, concentration difficulties and psychosomatic symptoms. The social life of the group can be very deprived and unhappy for isolated and rejected students. Conflicts with the teachers are identified as contributing to lowered interest and motivation in school work, but also detached and indifferent behaviours may affect motivation and self-confidence negatively. The theme of specific and individual risks emerged in nine studies. Among students that experienced learning disability (dyslexia) secondary emotional problems had been common. Having a disability that influences the social behaviour may increase the risk to be victimized by peers. The students reported that the victimizations caused school difficulties, sickness, absenteeism and depression. Other social problems (family conflicts, abuse, addiction, refugee status) could also make the students more easily exposed to negative experiences at school.

Some reflections: The studies reporting views of younger children on the matters of this review were less well represented. The negative experiences may be expressed in rather cautious terms by younger children. The experiences of the students change when they grow older, go through developmental processes and encounter different educational situations. Several developmental trajectories can be identified. The systematic review of qualitative studies is a valuable methodological approach that can be applied in the field of special educational needs.

PAPER PRESENTATION

Success at adult education: The situation of 16 to 18 year-old students with special needs

Nadia Rousseau, Université du Québec à Trois-Rivières, Canada; Karen Tetreault, Université du Québec à Trois-Rivières, Canada; Ghislain Samson, Université du Québec à Trois-Rivières, Canada; Sylvie Frechette, Université du Québec à Trois-Rivières, Canada

Many students with special needs leave high school before getting a diploma but reconnect with school through adult education. However, very few studies examine the situations experienced by these students. Therefore, this study aims to document the factors explaining why youths with special needs register in adult education programs at the age of 16, and to describe and analyse the school experiences of these students until they leave adult education with or without diploma. A sample of 165 youths with special needs, registered in an adult education program, answered a questionnaire outlining their past, present and expected situation as students. Also 45 of them accepted to participate in focus groups. 59 youths who left the adult education participated in phone interviews discussing their adult student

experience and their expectations about the future. Factors explaining the shift from youth to adult education are presented in order of significance. Students report a very positive perception of their school experience at the adult education. Recommendations are made to maintain this positive perception of adult education.

Introduction

Many teenagers abandon school before getting a high school diploma. In 2007-2008, 25.7% of Quebec teenagers were not enrolled in school and had not completed high school (MELS, 2009). They are unlikely to find a job in this complex society without the minimum credentials required in the job market. An important decrease in available jobs for youths without a high school diploma has been observed in the past years (Vultur, 2003).

Many youths reconnect with school through adult education. A significant increase of registration has been observed. Indeed, the number of students enrolled in adult education has increased from 128,200 in 1999-2000 to 158,793 in 2005-2006 (CSE, 2008). Many of them are students with special needs. Unfortunately, very few Canadian or Quebec studies examine the situations experienced by youths with special needs enrolled in adult programs. Therefore, it is advisable to examine the matter.

Objectives:

1. Document the factors explaining why youths with special needs register in adult education programs at the age of 16
2. Describe and analyse the school experiences of these students until they leave adult education with or without diploma.

Theoretical framework

Students that drop out of general education give the following reasons: lack of motivation, academic reasons, personal or family related issues, hoping to earn a living or have a job, their training perceived as completed, wanting to continue their schooling elsewhere, and repeated academic failures. (Potvin et al 2004). These reasons are associated with a number of challenging characteristics listed in several studies relating to dropouts : male gender, unproductive coping strategies, low self-esteem, poor social skills, negative perception of school, academic difficulties (especially in writing and reading), lack of motivation, behaviour problems (Fortin, Potvin & Royer, 2000), and negative school experiences (Rousseau, 2005). Finally, negative class atmosphere, negative teacher-students relationship and negative teachers' attitudes towards students with special needs (Potvin, 2005) are also associated with dropping-out. Many dropouts will register to the adult education in order to get a first diploma.

Methodology

A microethnographic analysis of case studies is conducted.

a) Participants and procedure

First objective

The sample is composed of 165 youths with special needs in high school school and registered in an adult education program in autumn 2007. They answer a questionnaire containing mainly metaphors (see Steinhoff and Owens, 1989) outlining their past, present and expected situation as students. Also 45 of them participate in focus groups.

Second objective

59 youths of the above sample that left the adult program with or without a diploma also participate in a twenty-minute phone interview on their adult student experience and their expectations about their future.

b) Data source

Two independent coders conduct a qualitative network approach of analysis that implies an inductive coding. The Cohen's Kappa coefficient of inter-rater agreement is 0.82. Frequencies are calculated in terms of proportion of meaning units in interviews.

Findings and discussion

According to frequency accounts, factors explaining the shift from youth to adult education are presented in order of significance in three broad themes: negative high school experiences, possibility of getting credits or a diploma, individual students' characteristics. Factors associated specifically with adult education are fulfillment of distal (getting a job) and proximal (getting a diploma) objectives. Factors associated with school are individual support, respect of individual learning pace, less stress and anxiety, and hope of success. Factors that explain leaving adult education without certification are the following: employment and persistence of school problems.

The participating youths with special needs left high school for adult education because they do not like school. The negative feelings are stronger with those in special education classes. When leaving adult education, they all have,

without exception, a very positive perception of their school experience, which represents a complete turnover. Students report working at their own pace in their books. Individual progress is monitored without references to the group. Moreover, positive feedback is given frequently and without prejudice. Unlike common belief, these students are persevering.

Conclusion and educational significance of the study

An increasing number of high school students who experience academic difficulties switch to adult education to get a high school diploma or the credits required for professional training. Throughout their schooling, they persist to overcome obstacles and progress at their own pace. Recommendations are made to maintain this positive perception of adult education.

PAPER PRESENTATION

Can preschool education prevent the incidence of later emotional and behavioural difficulties?

Pamela Sammons, University of Oxford, United Kingdom; Yvonne Anders , University of Bamberg, Germany; Kathy Sylva, University of Oxford, United Kingdom; Edward Melhuish, University of London , United Kingdom; Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom; Brenda Taggart, University of London, United Kingdom

Drawing on a large data set collected as part of the Effective Provision of Preschool and Primary Education 3-11 Project (EPPE 3-11) this paper looks at children identified as showing special educational needs in England at age 10. The present study investigates which child, family and home predict primary teachers' identification of children's SEN status in relation to emotional and behavioural difficulties at age 10 using logistic regression models. Further, the analyses explore whether children's earlier preschool experience is related to later incidence of SEN. The sample consists of 2509 EPPE3-11 children. 8.3 % of the children were identified by their teachers as showing SEN related to emotional or behavioural problems. Early health problems or behavioural problems, having been a premature child, low maternal education, self employment of the mother, low socioeconomic status and eligibility for free school meals show to be risk factors for the identification of SEN at age 10. Also, boys have a higher risk than girls whereas child age has a protective impact. Analyses further showed that the quality of preschool attended still was significantly associated with SEN identification, even when other background factors were controlled. The results of the present study underline the continuing effect of preschool quality as a factor that has a specific role in reducing the likelihood of later emotional and behavioural problems. High quality preschool may be viewed as an effective intervention for enhancing resilience in young children.

Aims

More than 30 years ago the Warnock Report (Department of Education and Science,1978) suggested that about 20% of children would at some stage in their school career experience special needs of some kind. There has been much debate about this figure, which was largely based on teachers' estimates, but it still reflects current levels of SEN identification in England (e.g. Croll and Moses, 2003). The early identification of SEN in primary school is considered one important prerequisite for children to reach their full potential (Davie, 1996). But rather than relying solely on

strategies implemented in primary school, it may be more effective to investigate what influences children's development at an earlier age (in preschool). Preschool education programs which may promote better adjustment to school and school readiness (e.g. Magnuson et al., 2004; Sammons et al., 2008; Sylva et al., 2010) might therefore be hypothesised to be a means to help protect children from later being identified as having some form of SEN while they move through primary and secondary school. Only a few studies have investigated longer-term benefits of preschool education so far and very little attention has been paid to the question of whether preschool has particular benefits with respect to children with SEN or at risk of developing SEN (Anders et al., 2010; Taggart et al., 2006).

Drawing on a large data set collected as part of the Effective Provision of Preschool and Primary Education 3-11 Project (EPPE 3-11), - a major longitudinal study of preschool and primary school influences on children's developmental outcomes - this paper investigates children identified as showing special educational needs in England and explores the factors that help predict SEN status at age 10. The present study investigates which child, family and home factors predict primary teachers' identification of children's SEN status in relation to emotional and behavioural difficulties at age 10. Further, the analyses explore whether children's earlier preschool experience is still related to later incidence of SEN.

Methodology

Sample

All data are drawn from EPPE3-11, which followed children's cognitive and social/behavioural development between the ages of 3 and 11 in England and was funded by the Department of Children, Schools and Families (DCSF). The project collected a wide range of data on over 3000 children, their background and the preschool settings they attended. At each assessment of the longitudinal investigation, primary teachers completed a child social behavioural profile for each EPPE child and reported details of any SEN. This investigation uses the child profiles completed at the end of Year 5 (age 10). The sample for this study consists of 2509 EPPE3-11 children with a valid profile.

Measures

Outcome measure

Teacher reported on present SEN in the child profiles. The current analyses focus on special needs related to emotional and behavioural difficulties.

Predictors

Child factors included gender, English as additional language (EAL), age in months, ethnic group, birth weight, early behavioural problems, number of early health problems and number of early developmental problems as reported by the parents in preschool interviews, premature child and number of siblings.

Family factors included family structure, parents' employment status, parental education, family salary at time of preschool education, family SES and child eligibility for FSM (a proxy measure for low income).

Parent-child activities and routines during the preschool years which provide an indication of aspects of the early years home learning environment (HLE), such as reading to the child, listening to the child read, teaching songs and nursery rhymes etc, were aggregated to a scale measure of the quality of HLE (Melhuish et al., 2008).

Preschool measures: The duration of preschool attendance and the quality (based on environment ratings using ECERS-R and ECERS-E) and effectiveness of the preschool centre were regarded as potentially protective factors and tested as potential protective factors.

Statistical analysis

First, all child, family and home characteristics were tested as potential risk or protective factors for SEN. Stepwise analyses were conducted and only significant variables were retained in the models. Subsequently, the impact of indicators of preschool education was tested individually in logistic regression models controlling for all statistically significant variables retained in the background model. Standard errors adjusted for the multilevel structure of the data were estimated.

Findings

8.3 % of the children were identified by their teachers as showing SEN related to emotional or behavioural problems. Early health problems, behavioural problems in the early years, having been a premature child, low maternal education, self employment of the mother, low socioeconomic status and eligibility for free school meals show to be risk factors for the identification of SEN at age 10. Also, boys have a higher risk than girls whereas child age has a protective impact with older children in the sample being less likely identified as SEN. The quality of HLE is not significantly related to SEN identification. With respect to the influence of preschool experience, analyses revealed that the most basic indicator – preschool attendance versus no preschool – was not found to be significantly related to SEN identification when other background variables were controlled. The same holds for duration of preschool

attendance and preschool centre effectiveness. In contrast the quality of preschool attended still was significantly associated with SEN identification, even when other background factors were controlled.

Theoretical and educational significance of the research

The results of the present study suggest that a range of preventive strategies that support children's development in the early years may improve 'school readiness' and therefore reduce the number of children who may be at risk of developing SEN in later years. An important point concerns the continuing effect of preschool quality as a factor that has a specific role in reducing the likelihood of later emotional and behavioural problems. High quality preschool may be viewed as an effective intervention for enhancing resilience in young children. The findings of the study are highly relevant to educational policy-making and the politics of change and improvement.

PAPER PRESENTATION

PowerPoint Does Not Make Us Stupid – But Extensive Slides Impair Recall of Oral Information!

Christof Wecker, University of Munich, Germany

This study investigated whether information presented on slides is more easily recalled than information presented orally, whether information presented orally is recalled more easily if concise slides are presented than if extensive slides are presented, whether concise and extensive slides are superior to purely oral presentation overall and whether any such effect of the presentation mode can be explained by differences in cognitive load. A field study with a one-factorial design with the conditions no slides, concise slides and excessive slides was conducted in tutorials about literature search and supply. Cognitive load as well as recall of information presented orally and information presented on slides were measured separately in all three conditions. The results show no general negative effect of slides with respect to the recall of orally presented information, but a superiority of concise slides compared to extensive slides with respect to orally presented information and compared to no slides with respect to overall recall of information. Information presented on slides is recalled more easily than orally presented information. Differences in cognitive load can be ruled out as explanations for any of these effects. Given these findings it seems advisable to keep presentations concise, but more research is needed in order to delineate the optimal amount and kinds of content on slides.

Presentation software has become ubiquitous in educational institutions. However a fear that "PowerPoint makes us stupid" (Gralla, 2010) has been voiced. Research evidence about the effects of the use and of design features of slides on cognitive learning outcomes is sparse. In one study a negative effect of a PowerPoint lecture compared to a traditional lecture was found with respect to the recall of information that was presented exclusively orally, with recall for oral information being as low in the condition with electronic slides as in a condition that did not receive any instruction on the topic (Savoy, Proctor & Salvendy, 2009). One potential explanation for this finding would be that the extensive use of slides might place to excessive demands on learners' cognitive resources. Another explanation could be that an extensive use of slides might induce the impression that only information presented on slides is important.

The present study aims to contribute to a broader research base about these issues and to provide some constraints for potential explanations for effects on recall of orally presented information. In particular, it addresses the following research questions: (1) How does the presentation of information on slides vs. purely oral presentation affect the recall of information? (2) How do concise vs. extensive slides affect the recall of information presented only orally and information presented on slides? (3) How does the presentation of information without slides, with concise slides and with extensive slides affect the overall recall of information? (4) Can differences in recall of information between presentation modes be due to differences in cognitive load?

Method Instructional setting.

The study was conducted in tutorials in which skills in searching and obtaining literature were taught. These started with a presentation about the scientific publication system and basics of literature research and supply, which was followed by a quiz that served as a posttest. Design. Three conditions were compared in a one-factorial design: No slides, concise slides and extensive slides. Four tutorial groups were nested within each condition. Independent variables. Content was constant across conditions. In the condition without slides all information in the presentation was given orally. In the conditions with slides the same information was presented orally, but in the condition with concise slides key points were listed on projected slides during some parts of the presentation, whereas in the condition with extensive slides also detailed information and key statements were projected on slides throughout the presentation. All slides contained a maximum of eight lines or six bullet points.

Dependent variables.

Recall of information was measured by 18 multiple choice items. One third of them covered information that was presented orally in all three conditions, information that was presented on slides in the condition with extensive slides, and information that was presented on slides in both conditions with slides, respectively. To equate these subtests, scores were z-standardized using the means and standard deviations from the condition in which all three kinds of information had been presented orally (no slides). Then two equally weighted scores were formed for recall of information presented only orally and for recall of information presented on slides separately for each condition. Cognitive load was measured by a single Likert type item with a nine-point answering scale. Participants. The sample comprised 294 freshers (86 % female, 14 % male) in a degree program in education from two subsequent years. Results (1) Recall of information presented on slides in the conditions with slides was higher than (i) recall of the same information in the condition without slides, $F(1; 282) = 14.48$; $p = .05$, and than (ii) recall of information presented only orally in the same conditions, $F(1; 181) = 43.78$; $p = .20$. (2) While there were no differences between concise and extensive slides with respect to the recall of information presented on slides, $F(1; 181) n. s.$, concise slides were superior to extensive slides with respect to the recall of information presented only orally, $F(1; 181) = 4.36$; $p = .02$. Although recall of orally presented information in the condition with concise slides was descriptively higher than in the condition without slides, these conditions did not differ significantly. (3) When recall for information presented only orally and for information presented on slides were weighted equally and combined to an overall indicator of recall of information, the three conditions differed in this respect, $F(2; 282) = 3.24$; $p = .02$. While concise slides were superior to no slides with respect to overall recall of information, $F(1; 191) = 5.53$; $p = .03$, the corresponding difference between extensive slides and no slides could not be secured against chance, $F(1; 192) = 1.47$; $n. s.$ (4) Cognitive load was generally moderate and did not differ between the three conditions, $F(2; 275) = 1.58$; $n. s.$

Discussion

A general negative effect of slides on recall of orally presented information as suggested by Savoy et al. (2009) could not be found. Instead, a positive effect of concise vs. extensive slides with respect to orally presented information was demonstrated. This effect cannot be explained by excessive demands on learners' cognitive resources. Presenting information on slides has an advantage with respect to the recall of these particular pieces of information. However, in many cases it seems unfeasible to put all the information one wants to convey on slides. Some information will almost certainly need to be presented orally. When equal value is attached to information irrespective of its presentation mode, concise slides appear superior to purely oral presentation whereas extensive slides do not. Therefore it seems advisable to keep slides concise. Future research has to delineate the boundaries of "conciseness".

PAPER PRESENTATION

Demonstration of Procedures in Face-to-Face Instruction: Effect of Animated Steps in Worked Examples

Christof Wecker, University of Munich, Germany

This paper deals with the question how worked examples for procedures should be demonstrated in face-to-face instructional situations. A plausible way of transferring the findings from research on worked examples to face-to-face instruction would be the use of presentation software. In particular, the requirement of making intermediary results transparent could be achieved by using animation functionalities for the stepwise presentation of intermediary results. The present study investigates whether such an animated stepwise presentation has a positive effect on procedure acquisition compared to a static presentation of the whole solution path.

A within-subjects design was implemented in a one-year university course about empirical research methods in two subsequent years: One of two procedures was demonstrated with animated stepwise presentation of intermediary results, whereas the other was demonstrated with a static presentation of the whole solution path. The order of the manipulation was counterbalanced. Procedure acquisition was measured in the regular examinations at the end of each term. The scores were z-standardized topic-wise in order to allow for within-subject comparisons of the two presentation modes. A significant positive effect of animated stepwise presentation of intermediary results compared to static presentation of the whole solution path was found, which was specific for the procedures in focus. This effect is remarkable given that it was obtained in a field study within a regular course where outcomes were measured several weeks after manipulation. In practice, intermediate steps should be presented stepwise using animation functionalities, which once was common in the age of the blackboard.

In many learning settings the acquisition of procedures such as performing statistical tests is a main goal of instruction. A central source for the acquisition of a procedure is the study of worked examples, i. e. the induction of the procedure based on the trace of intermediary results of the solution steps performed during its application (VanLehn, 1990): During the study of worked examples, the current knowledge of the procedure is applied to each intermediary result. Thereby, the subsequent intermediary result is either predicted or explained (anticipatory reasoning and principle-based explanation, cf. Renkl, 1997). An important prerequisite for this mechanism of procedure acquisition is specified by the so-called "show-work principle" (VanLehn, 1990): All intermediary results need to be transparent. Furthermore, step-wise presentation of intermediary results has been found to foster learning (Renkl & Atkinson, 2002). In face-to-face instructional settings, presenting the types of worked examples used in laboratory research often would appear somewhat strange. Instead, the more natural and common way of presenting worked examples is an instructor providing a demonstration of the procedure (cognitive modeling).

In fact, [o]ne could argue that studying worked examples is a type of observational learning" (van Gog & Rummel, 2010, p. 156). Therefore, the research literature on worked examples can be regarded as basic research that needs to be transferred to face-to-face demonstrations in practical application settings (Atkinson, Derry, Renkl, Wortham, 2000). A plausible way of transferring the findings from research on worked examples to face-to-face instruction would be the use of presentation software (e. g. PowerPoint) that has become ubiquitous anyway. In particular, the requirement of making intermediary results transparent could be achieved by using the animation functionalities of this kind of software for stepwise presentation.

The present study investigates whether such an animated stepwise presentation has a positive effect on procedure acquisition compared to a static presentation of the whole solution path. Method Instructional setting and content. The study was conducted as a field study in the context of a one-year university course about empirical research methods in two subsequent years during the winter and summer terms. Design and manipulation of the independent variable. A within-subjects design was implemented: Of two procedures (winter term: Cohen's kappa, summer term: t-test for independent samples), in each year one was demonstrated with animated stepwise presentation of intermediary results, whereas the other was demonstrated with a static presentation of the whole solution path. The order of the manipulation was counterbalanced across the two topics in the two years without changes in content or amount of accompanying verbal explanations.

Dependent variables.

Procedure acquisition was measured by calculation tasks in the regular examinations at the end of each term. In both cases, the occurrence of the steps of the procedure in the solutions was coded and counted (winter: Cronbach's $\alpha = .85$, summer: Cronbach's $\alpha = .90$). Furthermore, the unspecific learning outcomes (for the other topics of the course) were measured in these examination by means of 21 and 16 multiple choice items, respectively (winter: Cronbach's $\alpha = .63$, summer: Cronbach's $\alpha = .65$). Both measures were z-standardized using the means and standard deviations for the respective topic to allow for within-subjects comparison between the two manipulated conditions. Participants. The sample comprised 324 students from the lecture who participated in it for the first time and took both examinations in the same year. They were on average 21.4 years old ($SD = 3.2$); of them 88 % were female and 12 % were male.

Results

The z-standardized scores for procedure acquisition were higher for the topic covered with animated stepwise presentation of intermediary results than for the topic introduced with static presentation of the whole solution path was implemented, $t(323) = 2.25$, $p = .01$, $d = 0.12$. To rule out the possibility that this difference might be due to variations between terms confounded with the manipulation, the unspecific learning outcomes were compared in the same way. The z-standardized scores for this variable from the terms in which animated stepwise presentation of intermediary results with respect to the particular topics chosen was implemented were not higher than the z-standardized scores from the terms in which static presentation of the whole solution path was implemented, $t(323) = -1.83$, n. s. Rather, the descriptive results tended in the opposite direction.

Discussion

In line with research on worked examples (Renkl & Atkinson, 2002), these findings indicate that animated stepwise presentation of intermediary results is more effective for procedure acquisition than static presentation of the whole solution path when demonstrating a procedure. In particular, potential confounding that might occur in a field setting using intact courses could be ruled out by means of the within-subjects design and the test for the specificity of the effect for the topics selected for manipulation. The effect on procedure acquisition is remarkable in spite of its low magnitude given that it was obtained in the context of a field study within a regular university course where the

learning outcomes were measured several weeks after a rather small-scale manipulation. For instructional practice it might be concluded that when using presentation software for the demonstration of procedures, intermediate steps should be presented stepwise using the animation functionalities of the software. This was actually the typical way of presentation in the age of the blackboard, but in the age of slides it requires additional effort during preparation.

PAPER PRESENTATION

The Mere Exposure to a Problem Prepares Teacher Students for Learning

Inga Glogger, Institute of Psychology, Germany; Lars Holzapfel, Educational University of Freiburg, Germany; Elmar Offenwanger, University of Freiburg, Germany; Rolf Schwonke, University of Freiburg, Germany; Matthias Nuckles, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany

There are approaches that try to optimize receptive forms of learning and direct forms of instruction by problem-oriented activities (e.g., Schmidt et al., 1989; Schwartz & Bransford, 1998). Such approaches typically use generative group activities that are quite time consuming. These activities are thought to generate useful forms of prior knowledge. Simply knowing about target problems might, however, already sufficiently prepare for learning from direct instruction, as the goal of learning and the application context becomes salient. In an experimental pretest-posttest design, 89 student teachers learned about assessing learning strategies in students' learning journals by a computer-based learning environment. The problem-first group were shown an authentic problem (evaluating learning journals and giving feedback) prior to a "receptive" learning phase and they worked on the problem after the learning phase. The problem-after group received the problem subsequent to the learning phase and then worked on it. The open-ended questions of the posttest were coded for identification of learning strategies and their quality and for suggestions to students for improving strategies (i.e., feedback). Providing the problem first enhanced learning in terms of identifying learning strategies and their quality. Surprisingly, suggestions for improving learning strategies were made more often by the problem-after group, even though they did not identify strategies and their quality as well as the problem-first group. Hence, receiving an authentic problem prior to learning prepared teacher students to providing feedback that was based on specific observation rather than sparsely founded suggestions.

Aims of the study.

There are approaches that try to optimize receptive forms of learning and direct forms of instruction by problem-oriented activities (e.g., Schmidt, De Volder, DeGrave, Moust, & Patel, 1989; Schwartz & Bransford, 1998). These approaches typically use generative group activities that should lead to forms of prior knowledge that allows for subsequent elaborative processes. For example, Schmidt et al. activated prior knowledge by letting students discuss explanations for a problem central to the learning domain. There are little attempts to systematically study which features of the work on the problems are crucial. Does it actually require solving the problem? Attempts to solve the problem let learners encounter lacks of understanding or knowledge which is thought to be productive (Kapur, 2008, "productive failure"). Simply knowing about an authentic problem might, however, also hint to knowledge deficits. Knowing an authentic problem makes the goal for learning and the application context more salient. If knowing about a problem already suffices to prepare for learning from direct instruction, this option would be more time efficient.

In a previous study, teacher students learned about learning journals and how to diagnose learning strategies in such journals. By writing learning journals, students are encouraged to use learning strategies such as elaboration, organisation, and metacognitive strategies. For example, they could explain how a new concept relates to something they already knew (elaboration strategy). In order to apply learning journals as a method to foster learning strategies in students, teachers have to be able to identify learning strategies, their quality, and formulate useful feedback. Therefore, as an authentic starting problem, student teachers received learning journals of students. They were asked to find learning strategies and criteria for evaluating them. They showed more transfer than a control group that received explanations instead. In the present study, which was part of the research program "Bildungsforschung" ("Educational Research") of the Baden-Württemberg Stiftung, student teachers only knew about the authentic problem (i.e., evaluating and providing feedback on students' learning journal), but they worked on it after learning.

We expected that getting to know an authentic problem prior to learning enhances teacher students' diagnosis and feedback skills with respect to learning strategies.

Methods.

Eighty-nine student teachers (71 female, 18 male) from two equivalent seminars at a German University of Education participated in the study (title of the seminars: "Selected topics of mathematics instruction"). Two weeks prior to the intervention, they all worked on a pretest during their seminar. The pretest assessed diagnosis skills regarding learning strategies by three open questions. At the intervention, participants were randomly assigned to two conditions: (a) they received an authentic problem prior to learning with a computer-based learning environment and had 5 minutes to familiarize themselves with the problem (problem-first group, $n = 42$); (b) they received the same problem after learning (problem-after group, $n = 47$). The problem consisted of learning journal entries and a description of a situation ("Here you see two learning journal entries of two students. Your challenge is the identification of learning strategies and the formulation of a feedback to the students. Use the information from the learning environment. Before you start the learning environment, we would like to ask you to read the learning journal entries in detail (5 minutes)."). All participants learned in the computer-based learning environment for 30 minutes. In the learning environment, the diagnosis of elaboration strategies in learning journals was taught. Providing feedback was not specifically taught. After learning, the problem-first group had 10 minutes to solve the problem, that is, to identify learning strategies in the learning journals and to write feedback to the students. The problem-after group now received the problem, read it carefully (5 minutes) and worked on it for 10 minutes, that is, time-on-task was equal across groups. The open-ended questions of the posttest were coded by two independent raters (ICCs $> .80$). Learning outcome scores were (1) the number of sections coded as "identify and feedback learning strategies and their quality" and (2) the number of sections coded as "suggestions for improving learning strategies".

Results.

Teacher students who first familiarized themselves to the authentic problem achieved higher scores in identify ($F(1, 87) = 4.91$, $p = .029$, $\eta^2 = .05$). Suggestions, however, were made more often by the problem-after group ($F(1, 87) = 14.24$, $p = .001$). Prior knowledge was not significantly related to the learning outcome scores.

Theoretical and educational significance. Research on preparation to learn from direct forms of instruction used time-consuming instructional methods. Results of this study suggest that adult learners such as student teachers, however, can be prepared by the mere exposure to a problem taken from their professional context. The phase of (un)productive failure while struggling with a problem might not be necessary for all kinds of learners.

Unexpectedly, the problem-after group gave more suggestions to students how to improve their learning strategies even though they were less successful than the problem-first group in identifying learning strategies and explaining why the learning strategies were suboptimal. However, well-grounded specific and, thereby, helpful (Shute, 2008) suggestions can scarcely be made without detailed identification of learning strategies and their quality. We will reanalyse the suggestions in order to test if the problem-after group's suggestions were of lower quality than the suggestions of the problem-first group. In summary, receiving an authentic problem prior to learning prepared teacher students to learn and transfer their knowledge to giving feedback that was based on specific observation.

PAPER PRESENTATION

Expository Instruction before Inquiry Learning: Fostering Understanding of "Undiscoverable" Theories

Alexander Rachel, University of Munich, Germany; Christof Wecker, University of Munich, Germany; Eva Heran-Dorr, University of Bamberg, Germany; Christine Waltner, University of Munich, Germany; Hartmut Wiesner, University of Munich, Germany; Frank Fischer, Universität München, Germany

Some scientific theories that students are supposed to learn through inquiry learning involve assumptions about unobservable theoretical entities and relations among them. This study investigated whether prior expository instruction and summary expository instruction can foster the understanding of these theories. In an experimental study with a 2x2-factorial design 604 high school students from 23 classes participated in an inquiry unit about

magnetism. Prior expository instruction fostered the understanding of the explanatory theory both in an immediate and a delayed posttest. Summaries produced an effect on understanding of the explanatory theory only in an immediate, but not in a delayed posttest. The findings suggest that prior expository instruction can provide learners with explanatory theories they can apply to phenomena observed during their inquiry activities and thereby foster the understanding of such explanatory theories.

One of the main goals of science education is to foster the understanding of scientific theories that can explain observable phenomena. Inquiry learning is regarded as functional for accomplishing this goal (de Jong, 2006). However, explanatory theories in science that students are supposed to learn often go beyond functional relationships among observable variables that can be discovered by observation in a straightforward way. For example, in phenomena related to magnetism, (theoretical) molecular magnets cannot be observed directly. Accordingly, the learners' hypothesis space (Klahr & Dunbar, 1988) will hardly contain assumptions about them, and they have little chance to discover them on their own. This suggests expository instruction about possible explanatory theories as an approach to foster theoretical understanding during inquiry learning. In principle, expository instruction can be provided prior to inquiry activities, but the same content can also be presented in a summary afterwards.

In the former case, learners could use these theories to explain the phenomena they encounter during inquiry activities, which could help them develop a robust understanding of them. In the latter case, however, this use of the theories is not possible: Without the opportunity to use them to make sense of the phenomena observed, learners may be less likely to build up a robust understanding of them. To test these assumptions, we conducted an empirical study to investigate the effects of prior expository instruction and summary expository instruction on the acquisition of understanding of scientific theories. We hypothesized that prior expository instruction improves understanding of scientific theories compared to no prior expository instruction in a test immediately after the learning phase as well as several weeks later. We further expected that summary expository instruction improves understanding of scientific theories compared to no summary expository instruction only in a test immediately after the learning phase, but not several weeks later.

Methods and data sources

Participants. The participants in this study were 604 German high school students from 23 7th grade classes (60 % female, 40 % male; age: $M = 12.66$, $SD = 0.59$). **Design.** Five to six intact classes were randomly assigned to each condition of a 2x2-factorial design with prior expository instruction (without/with) and summary expository instruction (without/with) as independent variables. **Procedure and learning environment.** Whole classes of students first completed a 10 minute pretest. Then they worked on an inquiry unit about magnetism for 100 minutes. In all conditions the students conducted hands-on experiments in dyads at up to eleven learning stations. They completed an immediate 20 minute posttest and about two months later a 20 minute delayed posttest in their classrooms.

Independent variables.

In the conditions with prior expository instruction, first a 25-minute introduction to the theoretical background of magnetism was provided by a teacher. No such introduction was given in the conditions without prior expository instruction. In the conditions with summary expository instruction a 25-minute teacher-led wrap-up phase about the same topics as in prior expository instruction took place afterwards, while there was no such phase in the conditions without summary expository instruction. **Dependent variable.** Understanding of the scientific theory of magnetism was measured by means of 16 multiple-choice and true-false items (immediate posttest $\alpha = .71$; delayed posttest $\alpha = .74$). A test for knowledge about functional relations among observable variables associated with magnetism was used as the pretest (13 items, $\alpha = .62$).

Statistical analysis.

Data were analyzed by means of single ANCOVAs with the respective posttest measure as the dependent variable, prior expository instruction and summary expository instruction as independent variables, class as a random factor nested within the cells of the design and the pretest measure for knowledge about functional relations among observable variables as a covariate. The significance level was set to 5 %. Results A main effect of prior expository instruction in favour of the conditions with prior expository instruction compared to the ones without prior expository instruction could be detected in the immediate posttest, $F(1; 19.14) = 12.39$; $p = .002$; partial $\eta^2 = .05$. An analogous main effect of prior expository instruction was found in the delayed posttest, $F(1; 19.37) = 10.87$; $p = .004$; partial $\eta^2 = .03$. Furthermore, a main effect of summary expository instruction in favour of the conditions with summary expository instruction compared to the ones without summary expository instruction was found in the immediate posttest, $F(1; 19.12) = ; p = .001$; partial $\eta^2 = .06$. However, this effect disappeared at the delayed posttest, $F(1; 19.38)$ n. s. In both posttests, no significant interactions were found.

Discussion

These findings provide evidence for our argument that understanding of scientific theories that involve unobservable variables is less likely to be attained by inquiry activities without further support. Rather, learners benefit substantially by being introduced to the theories developed by scientists. The finding that a summary of the same content as provided by prior expository instruction did not produce a lasting effect on the understanding of scientific theory suggests that the effect of prior expository instruction is not simply a matter of being told the right answers. An explanation could be that prior expository instruction about theories that cover phenomena observed during hands-on experimentation can lead to the application of these theories during inquiry activities, thereby yielding deeper theoretical understanding. Overall, the study supports the argument that elements of direct instruction might play an important role in inquiry learning (cf. Klahr & Nigam, 2004), while still highlighting the importance of phases of inquiry in which learners can apply the theories to be learned. Teachers implementing inquiry learning would be well advised to reflect about the chances their students actually have to find out by inquiry what they are supposed to learn, and provide targeted support.

PAPER PRESENTATION

Interpersonal teacher behaviour: lesson associations with classroom social climate

Tim Mainhard, Utrecht University, Netherlands; Mieke Brekelmans, Utrecht University, Netherlands; Theo Wubbels, Utrecht University, Netherlands

The present study investigated whether the classroom social climate varies between lessons. Specifically, the within- and across-lesson associations of coercive and supportive teacher behaviour incidents with the classroom social climate were studied. Participants in the study were 48 Dutch secondary school teachers and their classes, that is, 1208 students. Multilevel process analyses showed that supportive behaviour incidents correlated with a positive social climate during the current lesson and the lesson a week later in terms of teacher interpersonal Affiliation. Supportive behaviour incidents did not, however, correlate with social climate in terms of teacher interpersonal Control. Coercive behaviour incidents correlated with disrupted teacher Affiliation during the current lesson and the lesson a week later, but did not virtually correlate to increased levels of a teacher's Control in the classroom.

How students perceive the classroom social climate, and especially the way students perceive their teachers interpersonally, is strongly related to student achievement and well-being (Davis, 2003; Wentzel 2002; Wubbels, Brekelmans, den Brok, & van Tartwijk, 2006). The more warm and supportive a teacher is, the more students report a sense of belonging and being engaged (Freeman, Anderman, & Jensen, 2007). On the other hand, if teachers are acting offensive and coercive learning is negatively affected, and students report more psychological and somatic complaints (Sava, 2002).

The aim of the present study is to examine how incidents of coercive and supportive teacher behaviour are associated with the variability of the classroom social climate teachers create. Studies which have investigated changes of the classroom climate (Mainhard, Brekelmans, Wubbels, & den Brok, 2010; Patrick, Anderman, Ryan, Edelin, & Midgley, 2001) have largely done so over rather extended periods of time (e.g., several months), thereby ignoring lesson-to-lesson variability. The present adds to the existing body of knowledge on classroom social climates by investigating these associations within (i.e., during a lesson) and across lessons; specifically, what is the association of coercive and supportive behaviour of a teacher with the classroom social climate one or two weeks later? Incidents of teacher coercion and supportive teacher behaviour may change classroom social climate temporarily or permanently.

Classroom Climate and teacher behaviour

In the present study, the social climate is conceived as the quality of social relations in classrooms. Collective students' perceptions of the teacher Control and Affiliation are utilized as an indicator of the climate. Building on a phenomenological point of view, students are considered as the most appropriate informants of their learning environment (c.f., Lýdtke, Robitzsch, Trautwein, & Kunter, 2009). Teachers with relative more Control and Affiliation provide, in terms of students motivation and learning outcomes, more effective classrooms (Brekelmans, Sleegers, & Fraser, 2000). The student Questionnaire on Teacher Interaction (QTI, Wubbels et al., 2006) was used to tap students' perceptions teacher Control and Affiliation (respectively: $\alpha = .80$ and $.93$; ICC1 = $.44$ and $.52$, ICC2 = $.93$ and $.95$).

Actions to gain control that students perceive as coercive negatively affect the social climate and student learning (Lewis (2001). Coercive discipline includes sarcasm, yelling in anger, embarrassing students, and punishment. On the other hand, using appropriate humour, providing clear and structured instruction, or undertaking activities students think are fun are factors that support a positive classroom social climate. A Teacher Behaviour Observation Checklist (TBOC) was developed, to collect student observations of teacher behaviour incidents (coercive: $\alpha = .81$, ICC1 = .58, ICC2 = .92.; supportive: $\alpha = .71$, ICC1 = .53, ICC2 = .91).

Hypotheses

In classrooms with more incidents of coercive teacher behaviour students perceive less Affiliation; teachers might gain Control because students comply with the teacher's display of power (Hypothesis 1).

Incidents of supportive behaviour positively correlate with students' perceptions of a teacher's Affiliation, but are also beneficial to the teacher's Control (Hypothesis 2).

Method

Participants and Procedure

48 Dutch secondary school teachers (26 females) and one of their classroom groups (1208 students, age $M = 14.09$, $SD = 1.47$). Teachers were asked to administered questionnaires on 9.31 ($SD = 2.35$) occasions during 4 month (i.e., 447 individual classroom lessons in total). Half of the students completed the QTI and the other students the TBOC. Thus, each time, a student focused on either teacher behaviour incidents or teacher Control and Affiliation to yield some independency in the applied measures.

Results

Multilevel process analysis was employed (van Doorn et al., 2008), which relates two or more simultaneously assessed concepts across time. This analysis is similar to multilevel modelling employing time varying covariates but without including a designated time variable as a predictor. Results are summarized in Table 1.

Discussion

Hypothesis 1

Frequently using coercive behaviour was associated with significantly lower teacher Affiliation. It immediately disrupted the social climate, and was associated with less Affiliation a week later. The use of coercive behaviour was associated with somewhat more Control in class, but acting coercively in two lessons in consecutive weeks occurred to counterbalance these associations.

Hypothesis 2

Frequent supportive behaviour was associated with more teacher Affiliation during the current lesson as was supportive behaviour one week earlier, but to a lesser extent. More frequent supportive behaviour however was hardly associated with teacher Control.

There were no differences found between classrooms in the associations between teacher behaviour and the social climate (i.e., random slopes). This suggests that the processes described here are comparable across classrooms.

Practical implications

Coercive teacher behaviour is very unlikely to go together with greater Control in the classroom. Teachers who engage in coercive behaviour may deliberately sacrifice Affiliation because they believe they will re-establish or consolidate their Control in the classroom. The present study shows that this assumption is not justified. Teachers should use small rather than intense corrections, behave as unaggressive as possible (Evertson & Weinstein, 2006), and should apply increased intensity of disciplinary actions only for intensified disruptive student behaviour (Cr   ton et al., 1989). Regarding supportive behaviour, although the effects we found were not substantial, we have shown that supportive behaviour pays off immediately and is an investment for the near future as well.

PAPER PRESENTATION

Dialogic interaction among primary pupils in a wiki-environment in science

Judith Kleine Staarman, University of Exeter, United Kingdom; Manoli Pifarre Turmo, University of Lleida, Spain

This paper describes the analysis of the collaborative process of a primary pupils' writing task with the aid of a Wiki environment. Students worked and contributed to the wiki in pairs. The aim of the project was to explore how a wiki may be used to support primary school pupils' collaborative interaction and to shed light on the complex process of collaboration and interaction, both in and around the Wiki environment.

Our study illustrates some of the challenges and the difficulties that students had to face in order to write a text collaboratively with a Wiki. We argue that students need to develop an intersubjective orientation towards others participants' perspectives, to be able to co-construct knowledge about a topic. For this purpose, the project utilised a "Thinking Together" – type approach to help students to develop an intersubjective orientation towards one another and to support the creation of a 'dialogic space' to co-construct new understanding.

We present our focus for the analysis of face-to-face students' interaction in order to contribute in the Wiki environment, which is based on a dialogic approach to collaboration. Our results illustrate how the thinking together approach became embedded in the Wiki environment and how in the context of a science project, it enabled the collaborative writing of a joint informative text about the science topic under investigation.

Our aim for this paper was to find out how, in a Wiki environment, students develop and maintain shared understanding of a science topic, and how students are taking each other's perspective into account. We also aimed to examine how the wiki environment itself may or may not support students in this process. To this end, we designed, implemented and evaluated a science project in which primary students used a Wiki environment, with the specific aim of establishing and supporting collaborative interaction, while engaging in a collaborative writing task. Students worked in pairs and also made their wiki contributions as pairs.

Our theoretical background is grounded in socio-cultural theory, which states that social interaction lies at the heart of all learning processes. From our perspective, participation in a collaborative activity requires that participants establish and maintain what Rogoff (1990) and Wertsch (1991) have termed intersubjectivity.

To enable and support collaborative learning, there are a number of particular relevant characteristics of wikis. First, wiki software enables the collaborative editing of texts and these texts are then available to the whole community of users. This means that the joint collaborative process and product is visible to all participants. Secondly, the wiki software allows two separate but related collaborative processes to happen simultaneously. The actual wiki content is written collaboratively on one page, while a tab leads to another page, in which participants may negotiate the actual content of the wiki. Thirdly, the collaborative writing process in a wiki environment is asynchronous, mediated and indirect, which gives participants the opportunity to reflect on what they read and write to respond/reply to their partners. And fourthly, all revisions to the wiki page are kept in the wiki history, enabling users to trace the development of the wiki and reflect on the changes in the collaborative work.

Although these features are characteristics of wiki design that may enhance the collaborative processes, it remains unclear which pedagogical approach could contribute most to successful collaborative learning processes using wikis and what difficulties and needs primary students would require in order to participate in the Web 2.0 global knowledge era.

The study took place in Lleida, Spain, in an urban primary school. Twenty-five 9-10 year old pupils participated in the study. Students worked together in pairs in the wiki environment to create a joint informative text about a science topic, together with 2 other pairs. We analyzed in depth the data collected during the seven wiki sessions. We video-taped, transcribed and analyzed face-to-face pairs' interaction while working in the wiki environment.

In this paper, we aim to answer the following research questions:

1. What type of peer's interaction occurs when they are working in a wiki environment? What features of dialogue are they using?
2. How does the face-to-face interaction of pupils support the interaction in the wiki-environment and the creation of a joint collaborative text.
3. What is the relationship between the pairs' collaborative communication and thinking as evidenced in their talk and their contributions in the wiki environment?

Our analysis approach has strong links with a methodological framework called Sociocultural Discourse Analysis (Mercer, 2005). The first stage of the analysis involved characterizing the type of interaction of students in and round the Wiki. The second stage of the analysis process consisted of searching for the presence of key words that may indicate reasoning and collaboration. For this reason, we used a computer-based concordance analysis programme (Wordsmith Tools).

For our analysis approach, we adopted a dialogic approach to studying the interaction of the students, and aimed to characterise the interaction process in terms of the students' intersubjective orientation. We based our analysis on the characterisation of talk in terms of Disputational, Cumulative and Exploratory, as proposed by Mercer and

colleagues (Mercer, Littleton and Wegerif, 2004). We argue that a dialogic approach such as this is needed to analyse interaction in a complex environment such as the one utilised in the current study, to be able to take into account the collaborative dimension of computer-supported collaborative learning.

Our data showed many episodes in which students presented a Disputational or more Cumulative orientation. The presence of these kinds of students' orientations could partially be explained in relation to the purposes of the task, it also indicates that the technology itself does not guarantee effective collaborative processes. It is therefore necessary to design an instructional approach that prepares students to use the wiki effectively and to develop students' awareness about thinking and working together in web 2.0 technologies. This result is line many voices that highlight students need a shift to a more participatory and collaborative culture of literacy practices (Wei-Ying, Hyo-Jeong & Seng-Chee, 2010). This shift needs also deep changes in the pedagogical practices that design the conditions to develop students' competences that eLearning 2.0 technologies require.

In contrast, our study also found episodes in which students presented a more Exploratory orientation. In the paper we will discuss what characteristics of the pedagogic design of the wiki environment used in our study might support students' joint interaction processes. Briefly, we stand out the next four. Firstly, the students' preparation to collaborate in a wiki environment using the "Thinking Together" approach was fruitful. Students used explicitly many of the features of the program in their collaborative talk. Secondly, every pair presented their own ideas in an initial text in the wiki environment, which was helpful in giving a 'voice' to all members of the group from the beginning of the collaborative work as it enabled all the pairs to be orientated to each other's ideas from the start. Thirdly, the students were all the time working with an artefact that was created as the product of their active participation. This may have encouraged users to examine others' opinions more closely, take them into consideration and increase their knowledge more deeply. Fourthly, the asynchronous nature of the collaborative processes in the wiki seems to have supported co-reflective processes about others' ideas, thoughts, arguments and information, which, in turn, lead to reconstruction and reorganization of experience.

PAPER PRESENTATION

Doing instructions. Exploring instructions in multilingual classroom interaction

Oliver St John, Orebro university, Sweden, Sweden, Sangeeta Bagga-Gupta, University of Orebro, Sweden

Doing instructions. Exploring instructions in multilingual classroom interaction

The aim of this study is to explore what might distinguish instructions from other kinds of classroom interaction in different classroom settings. Data is taken from video recordings of entire lessons in English, Home Economics, French and Maths as part of ethnographic fieldwork at an international secondary school in Sweden. CA analytic procedures have been adopted and developed. A complementary source of data is ethnographic field notes.

Preliminary findings suggest that instructions exhibit distinct features which participants orient to as instructions while relating them structurally to lessons as a whole. In doing instructions, teachers routinely mark their beginnings with 'openings' (e.g. calling the class to attention), sequence a variety of components (e.g. invoking past lesson activity) and conduct recurrent ways of bringing them to a close (e.g. giving a summary). Data makes evident certain kinds of boundary markers framing instructions as well as reinforced discourse, measured pace and the prominence of kinetic and gestural synchronized signals during such activity. A comparison of doing instructions across subjects suggests that the learning of any subject is, to a significant degree, language learning.

The pedagogic significance of such studies is to encourage investment in instructions as not simply communication for cueing other learning tasks, but as platforms for supporting task-related language learning, student engagement, the negotiation of common purpose, cohesion between different (parts of) lessons, the creation of meaningful entry points, etc. In short, an environment for co-constructing meaning and understanding for tasks.

Doing instructions. Exploring instructions in multilingual classroom interaction

The 's' on the end of 'instruction' indicates the distinction made in teaching methodology arenas between explaining subject content (instruction) and explaining what to do (giving instructions) (e.g. Kerry and Wilding, 2004). 'Instruction' has often been equated with learning (Säljö, 2005:13) while 'giving instructions' has been viewed as prior or incidental to learning per se, as an activity whose value is attached to the greater cause it serves. While the view that the main purpose of instructions is to prepare the way for forthcoming learning activity has some validity, it masks the complexity of the relationship between giving instructions and other teaching routines and activities that structure classroom lessons (see Richards & Lockhart, 1996). Views of learning as integral to social practice (Lave &

Wenger, 1991), as participation and acquisition (Sfard, 1998) and as interaction (Firth & Wagner, 1997; 2007) challenge an assumed distinction between a non-learning preliminary and learning proper as untenable.

The aim of this study is to explore what might distinguish instructions from other kinds of classroom interaction, such as transitions or teacher-presented instruction, in different classroom settings. Aspects which observations in this study have suggested may be relevant to the distinctive identity of 'giving instructions' include discursive composition, boundary markers, techniques used by participants to make meanings clear and constraints on or opportunities for interaction.

This study is part of a larger analysis of lesson phases using video documentation of eighth-grade lessons recorded during ethnographic fieldwork at an international secondary school in Sweden. Video data for the study has been selected from sixteen English, Home Economics, French and Maths lessons. In pursuit of an emic perspective, CA analytic procedures have been adopted and developed by amplifying CA transcript conventions in order to widen the aperture on some of the finely-tuned visually-mediated communicative moves configuring classroom interaction. This multi-track transcription system aims to make available for analysis not only speech, but the printed, written language, bodily conduct and positions in relation to artefacts and other environmental resources in the classroom (see Bagga-Gupta & St John, 2010, in preparation). As a complement to this fine-grained micro view, ethnographic field notes serve as a bridge to possible broader significations in the analysis.

Preliminary findings suggest that instructions exhibit distinct features which participants orient to as instructions while relating them structurally to lessons as a whole. In doing instructions, teachers routinely mark their beginnings with 'openings' when they call the class to attention, announce an imminent task or preview what the 'instructions' are intended to explain or achieve. After beginning, teachers sequence a variety of components including invoking past lesson activity, use of artefacts such as books and whiteboards, categorizing or labelling tasks, directives in steps or stages, prospectively projected sample utterances to illustrate specific activity, examples of task-related choices the students are to make and task assessment criteria. The data also indicates that teachers conduct recurrent ways of bringing instructions to a close, such as giving a summary, managing role distribution or delivering a directive to begin the task.

Data makes evident teacher use of oral expressions (e.g. ok) body movements (e.g. claps) and orientations to classroom artefacts (e.g. books) as boundary markers between instructions and other activities. Talk tends to be well reinforced by paraphrases, double-layered in some cases, while the pace tends to be more measured and the use of synchronized kinetic and gestural signals is a prominent part of the concerted communicative action.

Indeed it is evident that the internal structure of instructions bears many of the features related to the organization of a whole lesson. A picture of task instructions as a miniature model of a lesson suggests that learning has just as much chance to thrive during the doing of instructions as it might in any other component part of a lesson. Cross-subject comparisons of doing instructions showcase that the way language is used in classrooms provides a basis for relating lessons along language continua rather than separating some as 'language' lessons and others in terms of non-language learning lessons. Since the different subjects and disciplines of school are constituted by and generate their own vocabularies and conceptual lexical labels, the learning of any subject is, to a significant degree, language learning.

The pedagogic significance of such studies is to encourage investment in doing instructions as not simply communication for cueing other learning tasks, but as a platform for supporting task-related language learning, student engagement, the negotiation of common purpose, cohesion between different (parts of) lessons, the creation of meaningful entry points, etc. In short, an environment for co-constructing meaning and understanding for tasks. Such an investment will make better sense if giving instructions is viewed not as a set of directions or step-by-step guide, for example, on how to assemble a piece of furniture or operate an appliance, but as one of the steps integral to and inseparable from the process of realizing all the steps.

PAPER PRESENTATION

Instructional Explanations When Introducing the Pythagorean Theorem: A Case Study

Daniela Jimenez, German Institute for International Educational Research, Germany; Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

Instructional Explanations in mathematics lessons remain a common practice and a typical discourse form though mathematics education has gone through dramatic changes in the last decades. The role of explanations seems to be particularly important when students are learning a new content, because explanations are a mean of conveying mathematical knowledge (Perry, 2000).

The aim of the present study is to characterize effective instructional explanations in videotaped mathematics lessons when introducing the Pythagorean Theorem. The case study was carried out in the context of a broader study including tests of mathematical understanding taken to the students immediately before and after the videotaped lesson unit. The 3 classes examined here were selected according to their learning outcomes under control of their previous knowledge. The results suggest that effective instructional explanations are based on concrete graphic support, showing flexibility in rewording and linking with previous knowledge. Besides, they include concrete applications of the Theorem and examples of its usefulness in everyday life. Even though these findings don't allow generalization, they could suggest that effective instructional explanations contribute to instructional quality.

Background and Aim of the Study One of the most important shifts in mathematics learning and instruction in the last decades has taken place in the conception of the subject matter, changing from a perspective of mathematics as composed of concepts and skills to be learned, to a new one emphasising the mathematical modelling of the reality (De Corte, 2004). This shift has had natural implications on classroom processes, and changed instructional settings and practices. In that landscape instructional explanations are an interesting topic, since they remain being a typical form of classroom discourse, especially when new contents are introduced to the students (Perry, 2000). Instructional explanations can be defined as pedagogical actions in response to implicit or explicit questions provided by teachers or students (Leinhardt, 2001). Their main purpose is the understanding of a portion of subject matter and can be accomplished in different ways, including diverse degrees and sorts of interaction between teacher and one or more students (Kiel, 1999). This means that instructional explanations can appear in several contexts and also take different shapes according with the instructional setting in which they occur.

On one hand instructional explanations have been conceived as a critical issue in understanding mathematical concepts since they are an important communication form of mathematical knowledge (e.g., Perry, 2000). Additionally, it has been argued, that since explanations are a form of oral communication, they offer the teacher the possibility to monitor the students' understanding and provide, if necessary, additional information or discuss possible misunderstandings immediately (Duffy et al., 1986). In contrast to that, Wittwer & Renkl (2008) indicate that explanations are often unnecessary, since they don't really promote understanding. A possible underlying reason is that while explanations occur, the learner assumes a passive role only listening to the teacher, instead of engaging actively in his own learning process. To sum up, there is agreement about considering instructional explanations as a frequent issue within lessons, but there are contradictory positions about whether and how they contribute to promote understanding. We would like to argue that whether instructional explanations promote understanding or not depends rather on elements of the way how explanations take place than to their frequency or duration. Consequently, the only possibility to assess whether instructional explanations are effective or not is regarding carefully the context in which they occur.

The present paper aims to shed light in aspects related to success and failure of instructional explanations in mathematics lessons when introducing the Pythagorean Theorem. More specifically following research questions will be examined, namely, what characterizes instructional explanations in lessons in which a high promotion of mathematical understanding takes place compared to lessons in which a low promotion of mathematical understanding occurs? **Method** The data source is the Chilean implementation of the core-design of the study "Quality of instruction, learning and mathematical understanding" designed and carried out originally in Switzerland and Germany (2000-2006) by the German Institute for International Educational Research and the University of Zurich. The complete Chilean sample consists of 21 mathematics teachers of 7th grade classes and their respective 784 students,

which participated in the investigation along one school year. In every class 3 consecutive lessons about the introduction of the Pythagorean Theorem were videotaped. Tests of mathematical understanding were taken immediately before and after the videotaped lesson unit. 3 of those teachers were chosen in order to carry out the present case study, according with the results of the post-test (under control of the pre-test). The analyses for the case study were based on the theoretical phases of the videotaped lessons and their respective transcripts. They included following dimensions of the instructional explanations, (1) use of graphic support, (2) explanations are repeated/modified, (3) Pupils' participation and contribution to explanations, (4) check for understanding, (5) link with previous knowledge, (6) abstraction and usefulness of the Pythagorean Theorem. Results The findings show differences in most of the dimension analyzed. Effective explanations about the Pythagorean Theorem were supported by hands-on activities, not only performed by the pupils, but also by the teacher or shared with the whole class. Besides, explanations' repetitions include often new information and there's some evidence of flexibility by rewording and going in depth. The teacher continuously checks for understanding while explaining and links the new contents with previous knowledge, not only mentioning it when a step is missing, but also using it as context to embed the new contents. Finally, effective explanations about the Pythagorean Theorem include concrete applications and examples of its usefulness in everyday life. In contrast to that, less effective explanations include graphic support, but just as context and not as a concrete tool. Repetitions occur frequently, tend to be rigid and don't incorporate new information. The teacher checks for understanding only few times along the lesson and often implicitly. New contents were linked with previous knowledge strictly when needed, for example to solve an exercise, but not really clarifying which is the link and why it is necessary. Only few or none concrete applications of the Pythagorean Theorem were presented and its usefulness was limited to mathematical contexts. It's interesting to note, that there were no differences regarding the participation opportunities given to the pupils, mainly answering dichotomous questions or only with one word.

Discussion

It is possible to characterize effective instructional explanations and distinguish them from less effective ones, regarding to what extent they promote mathematical understanding. In other words, even if we don't aim to assume that the improvement in learning outcomes is only attributable to the explanations examined here, these findings could suggest that effective instructional explanations contribute to instructional quality. These finding were obtained in a case study and don't allow generalization, besides they refer to an introductory unit in one curricular content, facts that allow a thorough examination. However, it would be interesting to investigate to what extent such characteristics can be applied to other teaching contents or whether it is possible to define features that allow their valid and reliable measure in bigger samples..

PAPER PRESENTATION

Experienced and non-experienced e-tutors in Europe: Differences in supporting online collaboration
Birgitta Kopp, Ludwig-Maximilians-University, Germany; Maria Cristina Matteucci, University of Bologna, Italy;
Carlo Tomasetto, University of Bologna, Italy

In this study, we investigated differences between experienced and non-experienced European e-tutors in their support of online collaboration in practice. Therefore, we developed a questionnaire European e-tutors had to fill in to evaluate specific collaborative activities and to answer yes/no-questions regarding their intervention to support these collaborative activities. In respect of these collaborative activities, we distinguished between cognitive and social activities which are relevant for effective online collaboration.

Overall, we received answers of 78 e-learning experiences from 17 different European countries. Cluster analysis was conducted to determine groups of e-tutors who answered similar regarding the response type across the various categories of support activities. To validate the cluster solution, we compared the resulting two clusters on the basis of the experience of e-tutors. The results indicate that e-tutors with experience evaluate relevant cognitive activities more important for collaboration than e-tutors without experience. Furthermore, e-tutors with experience intervene more often to foster cognitive and social activities. These findings show the importance of expertise in e-tutoring: It seems that e-tutors with experience consider the importance of specific cognitive activities for effective online collaboration and that they also are more familiar in detecting dysfunctional social phenomena and in adequately intervening to avoid such phenomena. Therefore, for daily practice it seems to be necessary to train e-tutors in sensitizing them to the problems and pitfalls of online collaboration.

Objectives

This study investigates how experienced and non-experienced e-tutors differ in supporting collaborative online learning in practice. E-tutors received a questionnaire evaluating specific online activities and answering yes/no-questions whether they practically gave online support for these specific activities in their e-learning experiences.

Theoretical framework

E-tutors are very important for the support of their learners, because virtual collaboration is often more demanding for learners as they mostly have no experience with this way of learning. E-tutors are defined according to their main function, which is to supervise and support learners.

When we look at the support of e-tutors, the question is which collaborative activities they specifically foster. There are especially cognitive and social activities important for collaboration. Cognitive activities are knowledge exchange, online discussion, argumentation, collaborative problem solving, and considering different perspectives. Regarding social activities, the focus is on the motivation of the group members, interpersonal interaction, social influence processes and information processing.

Regarding the daily practice of e-tutors, the question arises how e-tutors support collaborative online learning. As research on the topic of expertise shows that experts differ from individuals without expertise in their way how they deal with problems, the question remains whether such differences in problem-handling are true for e-tutorial support in collaborative online learning.

Research question

Do experienced and non-experienced e-tutors differ in supporting online collaboration? As experienced e-tutors already know how collaboration in virtual learning environments functions, the assumption is that experienced e-tutors differ in their support from non-experienced e-tutors in that way that experienced e-tutors support collaborative online learning to a greater extent than non-experienced e-tutors.

Method

Sample

The sample included seventy-eight e-learning experiences from 17 different European countries. All e-tutors completed an online questionnaire regarding their e-learning experiences with collaborative learning. Participants were instructed to complete one questionnaire for each e-learning course.

Design of the Study

The study was a survey for e-tutors regarding their experiences in providing and supporting virtual collaboration which took place in July 2007. All e-tutors received access to an online questionnaire in their language and were asked to answer this questionnaire for every e-learning experience they offered.

Data sources

The online questionnaire which was developed for this purpose included two main dimensions: cognitive activities and social activities. Regarding the cognitive aspects of collaboration, the questionnaire included five main activities: knowledge exchange, online discussion, argumentation, collaborative problem solving, and considering different perspectives. To gain deeper insights into these activities, the questionnaire asked e-tutors whether they intervened to foster the specific collaborative activity and if yes, how they intervened and if no, why they did not intervene. Based on theoretical assumptions, social activities were evaluated mainly according to four processes: motivation of the group members, interpersonal interaction, social influencing factors and information processing. Regarding motivational aspects, two dimensions were considered, namely different group goals (2 items) and dysfunctional competition. Interpersonal interaction included phenomena such as dysfunctional interpersonal conflicts, balanced participation, and diffusion/lack of responsibility. Social influencing factors are ignoring minorities and putting pressure on group members. Information processing included the following: superficial discussion to avoid conflicts and addressing the e-tutor rather than group members (2 items). In the questionnaire again, e-tutors were first asked whether they intervened to avoid a dysfunctional phenomenon. If they answered yes, they were asked how they intervened, and if no, why they did not intervene.

Data analyses

We used the TwoStep cluster methodology to explore the data. The algorithm selected the optimal number of clusters based on either the Schwarz Bayesian Information Criterion (BIC) or the Akaike Information Criterion (AIC). Once clusters were established, we used separate t-tests and chi-square tests on variable(s) not used to form the clusters to test the validity of the cluster solution. We compared the clusters based on their response type across the various categories of support activities in terms of past experience of e-tutors, feedback practices and intervention rate.

Results

The cluster analysis identified two clusters whose stability was ascertained until 75 % of the sample size. Using a theoretically meaningful distinction, we report the data on the cognitive and on the social activities. Cluster 1 (n= 51; 65.4%) comprised e-tutors who evaluated cognitive activities more important (mean between 4.90 and 5.47) than e-tutors included in cluster 2 (n =24; 30.8%) (mean between 4.08 and 4.83). Furthermore, e-tutors of cluster 1 intervened between 40 and 48 times to foster cognitive activities in online collaboration while e-tutors of cluster 2 intervened only 8 to 14 times. Regarding social activities, according to Chi-Square-Tests again e-tutors of cluster 1 intervened in 9 of 11 times significantly more often than e-tutors of cluster 2.

Validity of the two cluster solutions was evaluated by testing group differences on variables that were theoretically or empirically related to each cluster. In particular we used as cluster validation items concerning the past experience of e-tutors in designing and realizing online courses. We expected e-tutors with experience to be over-represented in cluster 1, which was confirmed by a chi-square analysis. The great majority of e-tutors with past experience in designing and realizing e-learning courses belonged to cluster 1, $\chi^2(1, n = 75) = 11.75, p$

Discussion

Cluster analysis has shown that our sample of e-tutors significantly differ in evaluating the importance ascribed and in intervention rate concerning specific cognitive activities which are relevant for online collaboration. Subsequent analyses confirm that e-tutors who intervened more frequently in respect of fostering cognitive and social activities in virtual collaboration are those with past experience. Even though, overall the intervention rate for social activities is much lower than for cognitive activities (overall less than 50 per cent), e-tutors with experience are more able to detect dysfunctional phenomena and thus support their learners in working effectively together.

Educational significance

This study shows that experience in supporting e-learning groups is an essential precondition for evaluating relevant collaborative activities higher and in adequately intervening for fostering the interaction between group members. As this study asked e-tutors concerning their daily practice, it seems essential to train e-tutors in considering and detecting specific dysfunctional phenomena which may otherwise inhibit effective group work.

PAPER PRESENTATION

Scaffolding self-regulated learning: implications for the design of CBLEs

Anneline Devolder, Ghent University, Belgium; Johan van Braak, Ghent University, Belgium; Jo Tondeur, Ugent, Belgium

Research has shown that in order to learn effectively in computer-based learning environments (CBLEs), students need to show sufficient self-regulated learning skills (SRL). Unfortunately, not many students possess these necessary skills, so support needs to be provided towards the students when learning in these environments. A specific type of support we focus upon in this study are scaffolds. Scaffolds are technology-mediated systems that support the learners when performing a task (Sharma & Hannafin, 2007). In the field of scaffolding, little conceptual clarity exists. Moreover, it was shown that some specific scaffolds are only effective for some specific processes of SRL (Schraw, 2007). The aim of this study was to create an overview that makes it possible to compare the effectiveness of the different scaffolding types in support of the different processes of SRL. Therefore, we extended a review study in search of which specific scaffolds are proven to be effective in supporting SRL processes when gaining scientific knowledge. In order to support educational practice in the decisional process of choosing the right scaffolds, the results of this study are presented in an integrated framework of SRL.

Framework Computer-based learning environments (CBLEs) are becoming ubiquitous and more extensively used in education [1]. CBLEs comprise systemic features (e.g. open-ended in structure, non-linear) that offer new possibilities for learning and instruction like direct visualization and manipulation of complex topics [6]. In order to learn effectively with CBLEs, learners will need to show skilful engagement which can be captured as self-regulated learning (SRL) [15]. Students are self-regulated to the degree that they are metacognitively, motivationally, and behaviourally active participants in their own learning process [16]. Unfortunately, many students do not possess the necessary SRL-skills [3]. Therefore, students need to be supported when learning with CBLEs. Research has shown that scaffolds can give the necessary support to students lacking SRL-skills [1]. Recently, scaffolding is being described as "...the provision of technology-mediated support to learners as they engage in a specific learning task" [12, p.29]. Studies have shown that different types of scaffolds provide effective support for different processes of SRL [4]. This means that when CBLEs are being developed, the types of scaffolds will need to be selected with care. **Purpose & Method** In order to support educational practice in this decision making process, the aim of our study is to synthesize and schematize research results on the effects of scaffolding on the processes of SRL when learning in CBLEs. To fulfil this purpose, a systematic literature review was conducted [8]. Some general criteria were set to mark out our search (e.g. studies published since 2000). Second, inclusion and exclusion criteria were defined. According to these criteria, the database

Web of Science was searched through using terms like scaffold*AND self-regulated learning/self-regulat*. This search resulted in 24 articles. To present these results clearly, they were placed in an integrated framework of SRL [5] that is designed based on some central models of SRL as well as more current research relating the specific context of CBLEs towards these central models [e.g. 9,2,14].

Results

The results of this are presented in Table 1. Table 1. An integrated framework for effective scaffolds in support of processes of self-regulated learning(p: primary education; s: secondary education, h: higher education) CognitionMotivationBehaviourPhase 1:Task definition&Planning Guiding questions(h) Concept-mapping task (s,h) Preset goal hierarchy & goalDescription(s) 'Plan ahead' prompts(s) Searching features(p) High-order questions(h) Phase 2: MonitoringDiagrams (h) Hints & cognitive feedback (p) Self explanation prompts, reason-justification prompts, cues (s) Written question prompts (s) Guiding questions(h) Phase 3:ControlMetacognitive feedback &Strategy prompt(h) Concept-map template(p) Spoken advice (prompts)(s,h) Generating prompts(s)Processing prompts(s) Worked-out examples(s) Organization feature(s) (headings and written)Question prompts(s) Organization feature(s),Collaboration features(p),Maintenance features(p) Self-explanation prompt & Worked-out example(u) Spoken advice(h)Worked-out examples(s) Saving/viewing features(p) Concept-map(h) Strategic prompts & Graphic advance organizers(h)Phase 4:Reaction & reflection'Look back' prompts(h) From the 24 retrieved studies, 16 of them proofed that the use of certain scaffolds were effective when gaining scientific knowledge. Most of the studies examined scaffolds that support processes of cognitive regulation.

Results indicate that especially prompts are effective scaffolds for this area. Little effective scaffolds were found in the area of motivation and behaviour. The area of context in this framework was deleted, because no effective scaffolds were found. Another remarkable finding is that a small amount of these studies focuses on primary education, although this is a category of students possessing the least SRL-skills. As it can be seen in the framework and is confirmed by the literature, some scaffolds provide effective support for multiple processes of self-regulated learning [10]. ConclusionOn the basis of the discussed theoretical framework and method, we were able to list up the effective scaffolds influencing self-regulatory skills of students when learning in CBLEs. In the presentation, we will focus on the meaning of these scaffolds towards the design of future CBLEs while bringing personal characteristics (e.g. prior knowledge) and contextual characteristics (e.g. task, peers) into account.

PAPER PRESENTATION

Understanding the online information seeking practices of young people

Rebecca Eynon, University of Oxford , United Kingdom

As the Internet and other new technologies become embedded within the lives of young people there is a growing interest in the extent to which new technologies can enhance informal and formal learning. Effective online information seeking forms a key part of many of these potential learning opportunities. Using nationally representative survey data of 1000 young people, this paper aims to add to existing research by providing empirical data on how and why young people in Britain use the Internet for information seeking outside formal educational settings for homework and everyday life. Using path analysis, this paper will provide an overview of the ways young people are using the Internet for information seeking and examine the individual (e.g. age and gender), skill and contextual factors (e.g. parent, school and friends use of technology) that help to explain this behaviour. It is hoped that these findings may assist in the development of policies and practice to support young people to make the most effective use of the Internet for information seeking as part of their learning in a global networked society.

As the Internet and other new technologies become increasingly embedded within the lives of young people there is a growing interest in the extent to which new technologies can enhance informal and formal learning opportunities (e.g. Becta, 2008). Effective online information seeking forms a key part of many of these potential opportunities both to support formal education (e.g. for homework) and to support informal learning through everyday life information seeking (ELIS) (Savolainen, 1995).

While relatively little is known about how and why young people access information online in their daily lives for these purposes, it is likely that there is significant diversity in what, how and why young people search for information online.

This paper aims to add to existing research by providing empirical data on how and why young people in Britain use the Internet for information seeking outside formal educational settings for homework and ELIS. The data is based on a nationally representative face to face survey of 1000 young people in Britain aged 8, 12, 14 and 17-19. The survey was conducted between December 2008 and January 2009 utilising a stratified sampling strategy. The survey formed part of the Learner and their Context study, commissioned by Becta, which explored young people's views and experiences of new technologies outside school and was designed to inform the UK's Harnessing Technology Strategy. Using path analysis, this paper will provide an overview of the ways young people are using the Internet for information seeking and examine the factors that help to explain this behaviour. Drawing upon the learning ecology approach (Barron, 2006) and in line with a range of theoretical frameworks that stress the importance of understanding both individual and environmental factors when exploring Internet use (e.g. LaRose et al., 2001; McHale et al., 2009) this paper will examine the importance of: 1) individual factors, specifically, age and gender (Livingstone and Helper, 2007), socio economic factors and quality of access (Facer, Furlong, Furlong, and Sutherland, 2003); 2) networks of support, specifically, peer use of technology (Ito et al., 2008), parental engagement / regulation (Livingstone and Bober, 2005) and the school environment; and 3) skills and confidence, that is, self concept in learning new things and confidence in online information seeking skills (Broos and Roe, 2006). Each of these three areas are hypothesised to contribute (both directly and indirectly) to online information seeking. The overarching research question for this study is: what are the direct and indirect effects of individual and contextual factors on online information seeking for homework and everyday life?

The initial analysis demonstrates that parent's involvement in their child's uses of technology and school uses of the Internet have no direct effect on online information seeking either for homework or everyday life. However, they do have a direct effect on learner self-concept and / or online information seeking ability which are of key importance in understanding both kinds of online information seeking analysed here. Furthermore, individual characteristics which reflect basic factors of digital inclusion (such as home access to the Internet and / or socio economic status) continue to play an important role in understanding online information seeking for homework and / or everyday life. The findings indicate that there is a need for researchers to explore both offline factors (e.g. SES and learner self concept)

as well as online factors in understanding Internet use; and highlights the opportunities open to educators to support young people more in using the Internet for information seeking. It is hoped that these findings may assist in the development of policies and practice to support young people to make the most effective use of the Internet for information seeking as part of their learning in a global networked society.

PAPER PRESENTATION

Effects of constructivist teacher-led digital platform on learning achievement

Rosen Vigal, University of Haifa / Time To Know, Israel

This study explores the effects of a constructivist teacher-led one-to-one computing learning environment on elementary schools students' achievement in Mathematics and English Language Arts (ELA). The subjects were 59 4th grade students, who joined a Time To Know year-long program in Dallas, Texas and 68 4th grade students who learned in traditional settings. Findings indicated that learning with Time To Know program significantly enhanced students Mathematics and ELA achievements and contributed to development of Mathematics reasoning skills. In addition, the study showed that Time To Know program narrowed the gap between the low and high achievement students, as well as significantly promoted the academic outcomes of at-risk students, compared to the traditional settings. Overall, the findings indicated that intertwining digital content that is aligned with state standards and a constructivist-oriented teacher-led platform, enables a significant empowerment of teaching and learning processes.

Over past decade, there has been a growing interest in one-to-one laptop technology initiatives, whereby the teachers and the students have full access to a technology-rich learning environment (Bebbel, 2007; Gulek, & Demirtas, 2005; Jaillet, 2004; Lei & Zhao, 2008; O'Dwyer et al., 2008; Shapley et al., 2009; Silvernail & Gritter, 2005; Weston & Bain, 2010; Zucker & Light, 2009). The current study explores the effects of teaching and learning in the Time To Know program on Mathematics and ELA achievement of 4th grade students, compared to learning in more traditional setting.

Time To Know's teaching and learning environment is designed with a social-constructivist teacher-led approach to learning and teaching (Fosnot, 2005; Prawat & Folden, 1994; Roschelle, Pea, Hoadley, Gordin & Means, 2000; Von Glasersfeld, 1995). The program consists of five main components (Walters, Dede & Richard, 2009; Weiss & Bordelon, 2010): (a) Infrastructure: one-to-one laptop environment with a workstation for the teacher; (b) Interactive year-long core curriculum: Recommended sequences of interactive learning activities that are aligned with state standards. Teachers can modify these sequences by uploading their own "best practice" materials directly into the lesson flow; (c) Digital Teaching Platform (DTP): A platform that enables the teacher to conduct or plan a lesson, and to receive formative and summative assessment reports for data-driven instruction; (d) The platform also enables teachers to create their own content and adjust the recommended ready-made interactive learning activities to their teaching needs.; (e) Pedagogical support: Every teacher who joins the program takes part in comprehensive professional learning and ongoing guidance from an instructional coach.

The study addressed the following questions regarding the effects of the Time To Know program:

1. What is the impact of Time To Know program on reading, writing and Mathematics academic achievements, as measured by Texas Assessment of Knowledge Skills (TAKS) tests, compared to the traditional settings?
2. What is the impact of Time To Know program on academic achievements of at-risk students, compared to the traditional settings?
3. Do Time To Know students demonstrate greater Mathematics reasoning skills than control students?
4. Do lower performing Time To Know and control students (based on previous year TAKS scores) differ from higher performing students on Mathematics reasoning skills?

The study was based on the quantitative methodology using a quasi-experimental design (participation or non-participation in the Time To Know program). Pretest data were collected before the onset (April, 2009) of a Time To Know program, while post-test data were collected near the completion of the year-long school program (April, 2010). The study participants were 4th grade male and female students from four elementary schools from the Dallas-area district. Gender distribution was close to even. Two experimental schools were selected on the basis of two criteria: their participation in the Time To Know program and the same demographic background. Two control schools were purposively sampled to "match" the two Time To Know schools on the basis of known demographics (e.g., neighborhood characteristics, teacher characteristics, student characteristics). In all, there were 127 students who participated in the pre- and post-test data collection (59 experimental and 68 control students).

The instruments comprised on Mathematics, Reading and Writing and an adopted Mathematics reasoning test (HersHKovitz, in preparation). Mathematical reasoning refers to the ability to analyze mathematical situations and construct logical arguments (Francisco, & Maher, 2005; Stiff, & Curcio, 1999; Yackel, & Hanna, 2003). The Mathematics reasoning test was based on open-ended questions related to graphs and tables theme in 4th grade Texas curriculum that was taught in both the control and Time To Know classes.

The results indicated that participation in Time To Know (T2K) program contributed significantly to 4th grade students' academic outcomes in reading, writing and Mathematics, as measured by TAKS standardized tests. After controlling for gender, at-risk status, and 2009 reading TAKS scores (ANCOVA), the Time To Know students ($M=657.2$, $SD=88.3$) significantly outperformed the control students ($M=602.9$, $SD=104.4$) on the 2010 reading TAKS, $F(4, 95)=10.8$, p Time To Know students ($M=656.7$, $SD=83.0$) scored significantly higher than the control students ($M=625.1$, $SD=91.4$) on the Mathematics TAKS test, even after controlling for previous years TAKS scores (ANCOVA), gender, and at-risk status, $F(4,95)=6.5$, p

Although not significant, a trend was found in the context of at-risk students, showing that at-risk and non-at-risk students in the Time To Know classrooms score similarly. Whereas, in the control classrooms, the at-risk students Mathematics score much lower than the non at-risk population.

After controlling for students' third grade math TAKS scores, gender and at-risk status (ANCOVA), there was a statistically significant difference between the Time To Know and control students in the context of Mathematics reasoning (see Figure 9). Time To Know students ($M=35.7$, $SD=8.1$) far out-performed the control students ($M=24.3$, $SD=11.3$) on the Mathematics reasoning assessment overall ($F(4,95)=5.7$, p

Overall, the findings of the current study are showing the high potential of one-to-one computing learning environments, in which a comprehensive digital curriculum is combined with a constructivist-oriented teacher-led platform. Further research is recommended to examine qualitatively changes in teaching and learning practices underlie the effects of Time To Know program on academic outcomes, as well as the possible affective processes (i.e. engagement, motivation, self-regulated learning). In addition, given the relatively small sample, it is essential to conduct large-scale studies to examine the effects of comprehensive one-to-one laptop learning environments.

PAPER PRESENTATION

Effects of computer-based interventions to enhance the development of mental number representations
Andreas Obersteiner, Technische Universitat Munchen, Germany; Stefan Ufer, University of Munich, Germany;
Kristina Reiss, Technische Universitat Munchen, Germany

Cognitive psychological and neuropsychological research suggests two core cognitive systems of number processing, namely an object-file system for the exact representation of discrete objects and an analogue magnitude system allowing an approximate representation of quantities. In an intervention study we explored whether an exact or an approximate approach for fostering students' development of mental number representations was more successful. $N=46$ second grade students were tested in basic number processing (e.g., number comparison) before and after

seven computer-based intervention sessions. During the intervention students played one of two versions of a number game, requiring exact or approximate number processing. Results show that both the exact and the approximate condition led to improvements of basic number processing, without significant differences between these conditions. Process data revealed that both games were suitable for the students and did not differ in difficulty.

Theoretical background and aims

Cognitive psychological and neuropsychological research suggests that number processing relies on two “core systems” (Feigenson, Dehaene & Spelke, 2004), namely an object-file system for the exact representation of single objects and an analogue magnitude system for an approximate representation of quantities. Both systems seem to be innate and are responsible for early number learning. To enhance learning, mathematics education theories support the use of two kinds of manipulative materials representing exact numerosities using symmetric structures (e.g., a pegboard with two rows of ten pegs each) or analogue quantities (e.g., an empty number line). There is, however, no empirical evidence for the assumption that the use of such number representations has an effect on the development of students’ mental representations. The aim of our study is to explore whether an intervention using specific external number representations leads to improvements in basic number processing tasks, whether differential effects can be found for specific tasks, and whether computer games are an appropriate method for such an intervention.

Methods

In an intervention study with N=46 second grade students (mean age: 7;2 years) we used two different computer games (see Obersteiner, Ufer & Reiss, 2010). Both games were based on the “Number Race” (Wilson, Dehaene, Pinel, Revkin, Cohen & Cohen, 2006), an adaptive software with the aim of enhancing “number sense”. The two games were identical with respect to the overall conception. Depending on the level, the player had to solve number comparison tasks, calculation tasks, or number identification tasks with increasing task difficulty and time pressure. After each task, the player had to move his character on a game board by clicking on each square separately (“counting strategy”) or by clicking on the end square directly. However, the games differed in the way tasks were presented to the player. In the exact version numerosities were presented in symmetric structures and the tasks required exact number processing (e.g., exact calculation), while in the approximate version numerosities were presented without structures and the tasks required approximate number processing (e.g., approximate calculation). During the game, process data such as successful runs and number of clicks were logged. Before and after seven intervention sessions (30 minutes each) the students took a computer-based test of basic number processing (dot enumeration of structured and unstructured sets, number comparison, magnitude comparison, magnitude estimation, approximate calculation). Response times and accuracy rates were measured. Data from 3 students were excluded from further analysis due to absence in more than one intervention session.

Preliminary results

Both versions of the intervention program were suitable for the students and did not differ in general difficulty, as indicated by an equal mean number of games won by the students (22.1 for the exact version, 23.2 for the approximate version; $t(41)=-1.04$; $p=0.30$). Overall, students improved their number processing skills as indicated by reduced response times in all tasks of the post-test as compared to the pre-test. An analysis of variance with repeated measures showed that neither the differences between the two intervention groups nor the interaction terms with group reached significance for any task ($p>0.053$ for group differences, $p>0.108$ for interactions). Process data such as the number of clicks used to move the character on the game board revealed that students in the exact condition were more successful in directly clicking on the correct square as compared to students in the approximate condition (79% vs. 46% successful direct clicks; $t(41)=8.08$; $p<0.001$). This may reflect the successful use of structures by students in the exact condition.

Discussion

The two computer games were comparable in overall difficulty. They were an appropriate method to be used in an intervention study with an experimental design. Both games had positive effects on second grade students’ number processing abilities. However, as the present experiment was basically carried out to test the computer games, there was no control group, so that we do not know how specific these effects were. First results did not reveal group differences, indicating that both the exact and the approximate approach can be used to foster students’ number processing abilities. In the present study, we have tested a relatively small sample. After further developing the computer games we will test intervention effects in a larger sample of first grade students. So far, we have analysed differential effects on the group level only. In further analysis we will explore how individual factors such as working memory or visuo-spatial abilities may have influenced students’ test performances and their success during the intervention. A better understanding of such relations could help to develop individually tailored training for each individual student and is therefore of high relevance for mathematics education.

PAPER PRESENTATION

Students' use of tools in an undergraduate course: in search of tool-use patterns

Jan Elen, Katholieke Universiteit Leuven, Belgium; Geraldine Clarebout, Katholieke Universiteit Leuven, Belgium;

Griet Lust, Katholieke Universiteit Leuven, Belgium

Research in controlled settings has revealed that students' tool-use behavior is a complex self-regulated behavior that cannot be taken for granted (Azevedo, 2004). It remains however unclear if these results are replicated in an ecological setting characterized by learning tasks integrated into the natural flow of the study, enough time to learn to use the tools and with long-time retention measurements (Grabinger, 2008). This contribution focuses on students' tool-use in an ecological setting. An undergraduate course was selected as object of research because despite the popularity of blended courses, as an integration of course management systems into the traditional constellation, there is little insight in how students behave in those environments. More specifically, the study investigates how students use the whole toolset at their disposal, whether user-profiles can be found and what the effects of students' tool-use on performance are. Cluster analysis reveals three distinct tool-use patterns or user profiles: the no-users, the intensive users and the incoherent users. Results from multiple analyses of variance reveal that those tool-use patterns affect the performance significantly. The results indicate that despite the benefits of blended learning environments as illustrated in literature, not all students seem to profit from the opportunities that are provided. Similar as in controlled settings, the results seem to indicate that students' tool-use cannot be taken for granted. Hence, they call for more research into the influencing variables, student-and context related, and the performance effects.

Research in controlled settings (e.g. review Alevén et al, 2003) underlines the fact that adaptive tool-use, as using tools in accordance with perceived learning needs, is a self-regulated activity that cannot be taken for granted (Azevedo, 2005). However, most of the research is done in a controlled setting characterized by non-embedded learning tasks and a focus on short-time learning effects (Grabinger, 2008). It remains unclear whether these results are replicated in an ecological setting. The current study puts the tool-use research in an ecological setting and more specific in an undergraduate blended course where learning is supported by various combinations of classical face-to-face initiatives (e.g. lectures, learning sessions) and digital devices as provided through the CMS (e.g. exercises, practice quiz, discussion board). Despite the fact that students, in most cases, have control in using these tools, there is little insight in how students' deal with this learner control i.e. how they use the tools and how that affects their performance.

First evidence in the Elis, Marcus and Taylor (2003) study indicates that coherently using the total tool-set cannot be taken for granted. Students were unsure of how to approach the online tools in ways that are likely to maximize the learning benefits in blended experiences. With respect to students' use of CMS tools, different studies reveal that students differ in how they approach a specific CMS tool (e.g. Grabe & Christopherson, 2005) or multiple CMS tools (e.g. Hoskins & Van Hooff, 2005) and this affects their performance for the course. The studies are however focused on one or multiple CMS tools without investigating how students use the tools all together, i.e. tool-use patterns.

The current study investigates students' tool-use in a blended undergraduate course. Based on evidence regarding students' use of CMS tools, it is expected that tool-use differences will exist and similar with evidence in controlled settings (e.g. Jiang, Elen & Clarebout, 2009) they will reflect distinct tool-use patterns among students. At least three tool-use patterns are expected: the no-users, the incoherent users and the intensive users.

Method

The sample

The study runs in a first year undergraduate course at the department of 'Educational Sciences' at the Katholieke Universiteit Leuven. It contains 91% of the course-participants (n=159). There are 152 women and 8 men. Most of the students were 18 years (72.3%).

The undergraduate course: toolset

Additional to the lectures, a CMS was provided and a team of support staff was at students' disposal. The support staff organized three learning support sessions and a feedback session that students could use voluntarily. The CMS was designed using Blackboard. The access and the use of the learning environment were under control of the student.

The tool-use behavior was captured through log-files. Table 1 presents the tools and the log indicators that were used in this study.

Indicators of learning

Students' course performance was assessed by an exam (consisting of factual items, comprehension items and application items) and an assignment for which students had to argue about an educational proposition.

Results

Students' tool-use behavior: tool-use patterns

K-means cluster analysis in Matlab was performed. K-means cluster solutions with two to ten clusters were fitted using 1000 restarts (for a discussion of the use of K-means cluster analysis, see Steinley, 2003). On the basis of a scree-test, the three-cluster solution was selected as optimal solution since a clear demarcation point is visible after three clusters.

One-way analysis of variance reveals that all the tool-use variables have a significant impact in defining the three clusters, $p = .000$. Post-hoc comparisons are illustrated in figure 1. As the figure illustrates, those three clusters represent different tool-use behavior among students, characterized by different tool-choices and distinct intensity in using them.

Fig 1. Tool-use patterns

Learning effects of the tool-use patterns

Multiple analysis of variance reveal a main effect of students' tool-use behavior on the five performance indicators, $F(5,150) = .139$, $p = .005$. More specific, students' tool-use behavior influences their total course grade, $F(2,154) = 5.056$, $p = .007$, and their assignment score, $F(2, 154) = 7.767$, $p = .001$. As for the assignment score, students in cluster 3, $M = .09$, $SD = .96$, and in cluster 2, $M = .31$, $SD = .78$, outperform students in cluster 1, $M = -.41$, $SD = .94$. For the total course grade, a significant difference exists between students in cluster 1 and cluster 2. Students in cluster 2, $M = .29$, $SD = .89$ outperform students in cluster 1, $M = -.25$, $SD = .81$.

Discussion and conclusion

In line with our expectations, three usage patterns were found. Students in cluster 1 reflect no users, they did not use the available face-to-face and CMS tools. Students in cluster 2 are intensive users, they used all the available tools. Students in cluster 3 are incoherent users, they used the face-to-face tools, the course material outlines and the learning support. The two latter CMS tools have a clear link with the face-to-face context. The outline notes referred to the face-to-face lectures and the learning support referred to the learning support sessions.

A significant difference was found between the no-users and the other patterns in performance on the assignment and on the total course grade. Surprisingly, no significant differences were found between intensive and incoherent users. This result raises questions with respect to the functionality of some CMS tools, the consistency in the intensive users group, possible mediating variables and possible influencing student variables.

[1] Duration and mean time were expressed in seconds.

PAPER PRESENTATION

Where's the math? Locations of mathematical activity in classes with handheld technologies

Thomas Hillman, University of Gothenburg, Sweden

This presentation will examine the locations of mathematical activity in classrooms where handheld digital technologies are used. By drawing on Actor-Network theory, it will discuss the interactions between humans and materials within the sociotechnical networks of mathematics classrooms as they form in relation to Texas Instruments' TI-Nspire™ graphing calculator. The findings indicate that while many individual elements and connections exist within classroom sociotechnical networks, they operate as a complex interconnected whole. In particular, they suggest that the ways technologies are configured in mathematics classrooms have a profound effect on the mathematical practices within them but also suggest that this is far from a one-way phenomenon.

In this presentation, I will examine the locations of mathematical activity in classrooms where handheld digital technologies are used. By drawing on Actor-Network theory, I will discuss the interactions between humans and

materials within the sociotechnical networks of mathematics classrooms as they form in relation to Texas Instruments' TI-Nspire™ graphing calculator. TI-Nspire™ and related technologies are broadly advocated in curriculum documents and guidelines for teachers (Ontario Ministry of Education, 2005; Qualifications and Curriculum Authority, 2007). In addition, a growing body of mathematics education research suggests that these technologies help learners make connections with and between mathematical concepts and enrich their mathematical thinking (Kaput & Schorr, 2008). Given this support for the use of digital handheld technologies, it is important to unpack the ways they change the geography of mathematical activity in classrooms. In this presentation, I will address these changes by examining the role of TI-Nspire™ as a location of mathematical activity in relation to other materials, teachers and students.

Theoretical Perspective

As a theoretical perspective, I draw on Shaffer and Clinton's approach to understanding the relationship between digital technology and learners in mathematics classrooms (2006). In particular, following their lead I draw on the Activity-Theory concept of learning as activity that always involves cultural tools. This notion suggests that understanding the mediation of tools including technologies is vital to understanding learning itself (Saljo, Eklund & Makitalo, 2006). While Activity-Theory foregrounds the important role of tools in human activity, it considers technologies and humans to have an asymmetrical relationship. In this relationship, humans are assumed to act as agents and technologies are not (Shaffer and Clinton, 2006). This assumption may obscure the important role that particularly complex digital technologies such as TI-Nspire™ can have in mathematical learning. To address this issue, I turn to Actor-Network theory to conceptualize the relationships between humans and technology as part of social networks of humans and non-humans all mediating each other's activity (Latour, 2007). Within these sociotechnical networks the relationship between actors, both human and non-human, are conceptualised in reciprocal terms offering the notion that when interacting the capacity to act cannot be located in either party but instead emerges from their interaction (Latour, 2007). Together the combination of Actor-Network theory and Activity-Theory provide a useful perspective for examining the mediation of mathematical learning within networks of humans and materials.

Method

I observed two ninth grade mathematics classes in the Canadian province of Ontario, spending a week video recording in each classroom. Augmenting this, I conducted a series of recorded interviews with the teachers that began with an in-depth session focused on their experiences teaching with technology. Continuing the interviews, the teachers participated in a retrospective debriefing interview following each observed class. In addition, I interviewed two students from each classroom about their experiences with TI-Nspire™.

Following data collection, all video-recordings, interview transcripts and collected artefacts were examined using Interaction Analysis (Jordan & Henderson, 1995) as an analytic approach to describing the complex activities and interactions within the networks of mathematical activity. As a tool for performing this analysis, the qualitative data analysis software Transana was used. This powerful and flexible software supported a detailed examination and interlinking of all collected data, including video, in a single environment.

Findings

The findings that I will present show the complex ways that the introduction of a digital handheld technology such as TI-Nspire™ changes the geography of mathematical activity in classrooms. They speak to the relationships between TI-Nspire™, teachers, students, and a wide range of materials such as the computer lab, paper/pencil, the blackboard, and interactive whiteboards. All these materials served as locations of individual and shared mathematical activity in the two observed classrooms. While no material replaced any of the others with the introduction of TI-Nspire™, the networks of humans and materials in each classroom reconfigured in different ways that supported different mathematical activity.

While many individual elements and connections exist within classroom sociotechnical networks, the findings of this study indicate that they operate as a complex interconnected whole. In the two observed classrooms, it was particularly evident that the effects of the teachers' decisions to include TI-Nspire™ as part of their instructional practices were not limited to, for instance, the local relationship between student and handheld technology while completing an activity. They were instead extremely broad, influencing practices as diverse as the use of the computer lab and whole-class discussion of homework. The findings of this study suggest, that the ways technologies are arranged in mathematics classrooms have a profound effect on the mathematical practices within them but also suggest that this is far from a one-way phenomenon. While teachers have enormous influence through their choices

of what technological arrangements to use, the technologies themselves along with other elements of the classroom geography mediate these configurations and are highly interrelated.

PAPER PRESENTATION

The Adoption of Technology Innovations

Charalambos Vrasidas, CARDET - University of Nicosia , Cyprus; Christiana Aravi, CARDET, Cyprus; Katerina Theodoriodu, CARDET, Cyprus; Petros Panaou, UNIC - CARDET, Cyprus; Anastasia Economou, CPI, Cyprus; Ireneos Pattis, UNIC - CARDET, Cyprus

The adoption of innovations and technology in teaching and learning has been studied extensively. This paper presents findings from 3 year program that focused on the development of case studies of the use of ICT in the classroom and results from large-scale evaluations of technology initiatives in Cyprus public schools. A large-scale survey was conducted and 30 case studies were developed in order to examine the use of ICT by teachers, the effectiveness of teacher professional development and the challenges faced by practicing teachers with respect to the integration of Information and Communication Technologies (ICT) in the curricula. This paper discusses findings from the large scale survey and enriches the findings with qualitative data from the ethnographic case studies to illustrate insights on effective practices of ICT adoption in Cyprus education.

Introduction

Attempts to integrate technology in education provoke a variety of responses from teachers that range from enthusiasm and skepticism to fear and uncertainty. A long history of technology use in education reveals that the first reaction is to use new technology in the same traditional ways as the old technology. Old curricula and pedagogical approaches should be reformed, and if necessary replaced, to take advantage of the affordances of the new media.

Context

During the last two years, we were involved in two large scale evaluations of the Cyprus Education system and 5 developmental research programs supported by the Republic of Cyprus, EU Structural Funds, and the European Commission. The focus of these projects was on the adoption of ICT by K12 teachers and the effectiveness of existing professional development programs offered. One of the key issues that came out was the importance of both formal and informal ways for teacher lifelong learning, and the role that online environments can play to support them. In this paper, we present the summary of findings from evaluation work conducted to investigate the adoption of ICT in Cyprus public schools. This paper discusses findings from the large scale survey and enriches the findings with qualitative data from the ethnographic case studies to illustrate insights on effective practices of ICT integration in Cyprus education.

Research Methods

Participants

For the ethnographic case studies part of the projects, a total of 30 K12 schools participated (10 high schools, 20 primary schools). From each school we had one teacher as a case study. Each teacher and his/her class comprised of one case study in a variety of subjects. Teachers were chosen by the Ministry of Education based on the following

criteria: teachers must have participated in some of the professional development programs, represent all counties of Cyprus (geographical distribution), and they must have expressed interest to participate in the case studies.

Setting and Procedures

The project research team that investigated and evaluated the case studies was led by the international Research Center CARDET. A total of 55 researchers were involved in the research. In order to achieve homogeneity and ensure consistency in data collection and analysis, four half-day workshops were held during which all researchers received appropriate training. The evaluation work span a period of 20 months.

Research/Evaluation Questions

The study investigated a series of questions. For the purpose of this paper we focus on the following:

1. What factors affect teachers' efforts in technology integration?
2. How do teachers use ICT?
3. What barriers do teachers face in using technology in the classroom?

Data Collection, Instruments and Analysis

Data for this project were collected and analyzed using both quantitative and qualitative methods. Data were collected from the following sources:

- . Pre-interviews conducted with each teacher on the planning process for the unit to be implemented and the teacher expectations
- . Observations of at least ten lessons implemented by each teacher, which integrated technology in the classroom over a period of 6 weeks.
- . Teacher self-reflective journals
- . A teacher post-interview
- . Interview with each teacher's technology advisor
- . Interviews with at least 3 students from each case (selected with the help of the teacher)
- . Student pre and post-tests.
- . A large scale survey administered to K12 school teachers.

For the purpose of this paper, we focus on the findings from the large scale survey. The main objective of the survey was to analyze how teachers use technology in the classroom and what challenges they face. In the discussion below, we enrich the findings of the survey, with qualitative data from the 30 case studies. In order to develop the 8-page instrument for the survey, we relied heavily on the findings from the qualitative data (e.g. interviews and observations). In addition, we reviewed other instruments, and consulted with experts in the field. A first draft instrument was developed and pilot-tested with 10 teachers and 4 experts. Following the pilot, we finalized the instrument and administered it to a sample of 1051 teachers using stratified sampling procedures. The total population of primary school teachers in Cyprus, during 2008-2009 was 4150. We ensured that all counties and regions of Cyprus were represented from both rural and urban settings. The response rate of the questionnaire was 50.5% (531 out of 1051).

Data Analysis

During data analysis, we followed the inductive and deductive stages used in interpretive and case study research. After we collected and organized all the data, we read through the data three times and generated assertions. Once we generated assertions from the data as a whole, we entered the deductive stage. In this stage, we engaged in detailed examination of the data corpus and looked for data to confirm or disconfirm our assertions. Moreover, statistical analysis of quantitative data included tables and diagrams, whereas authentic excerpts were extracted from the qualitative data.

Results

Even though the authors have studied all research questions related to this study, this section discusses only findings on the factors that affect teachers' efforts in technology integration and the challenges they face. The findings presented in this paper shed light to the complexities of integrating ICT in teaching and learning. The research reported is the first of its kind conducted in the Cyprus context. Findings reveal that teachers are willing to integrate technology into their teaching practices. However, even though they realize the benefits of ICT integration, a lot of teachers today seem resistant to integrating technologies. This is due to several factors that were revealed through the findings, such as lack of time, the ill-structured design of the school curriculum, and lack of infrastructure

PAPER PRESENTATION

Depiction of Theme in Graphics: Its Influence in Expository Text

Robert Danielson, California State University, Chico, United States; Neil Schwartz, California State University, United States; Stefan Krause, University of Koblenz-Landau, Germany; Marie Lippmann, University of Dresden, Germany; Sevil Gonen, California State University, Chico, United States; Maryam Fallahi, California State University, Chico, United States; Steven Caldwell, California State University, Chico, United States

It is well documented that when graphics are paired with textual material, recall is enhanced. However, not all graphics operate in a similar fashion. Previous research has indicated that decorative graphics provide little to the overall understanding of textual material, while representative graphics help learners construct a cognitive model of text content. Recently, decorative graphics have been found to be more effective than previously thought. Graphics which highlight the underlying themes present in a narrative, yield comprehension that is comparatively deep. This effect has been found both immediately after reading and one week later. In the present investigation, 80 volunteers read an expository text about the conflict in Darfur in the presence of a graphic depicting either the text theme of civil war or genocide, or they saw a graphic depicting the geographic region of the conflict, or no graphic at all. Results showed that the graphics, when they are metaphors of the underlying text themes, greatly enhance recall of the text when compared to either the non-thematic graphic or no graphic at all. Results are discussed in terms of the way decorative graphics can be used to influence deep learning.

Examples of text paired with graphics are prolific throughout textbooks and the web. It is well understood that when the two appear together, performance is consistently better than text alone (Carney & Levin, 2002; Schnotz, 2002; Schnotz & Bannert, 2003; Mayer, 2003; Mayer, Hagerty, & Mayer, 2005; Lewalter, 2003). However, not all types of graphics function in the same way, and specific text-graphic combinations lead to different performance outcomes. Schnotz & Bannert (2003) demonstrated that unique graphics, paired with identical texts, create different mental representations of textual information, and poorly selected graphics interfere with mental model construction (Schnotz & Bannert, 2003). Furthermore, some graphics are less reliable in their effect on learning from text, particularly when employed to decorate a page. Levin, Anglin, and Carney (1987), in a meta-analytic review, found moderate to strong effect sizes for graphics employed to inform text by representing all or part of text content, but weak to non-existent effect sizes for graphics used for decoration.

We contend that graphics used to adorn text serve more than a simple decorative function. Instead, they convey information about the theme of a text and influence a learner's cognitive interaction with a passage (Schwartz, Battinich, Lieb & Mortensen, 2008; Schwartz, Lieb, Battinich & Kuinke, 2007). Schwartz & Collins (2008) demonstrated that decorative graphics are capable of activating the prior knowledge of learners in idiosyncratic but reliably predictable ways. Mortensen & Schwartz (2009) found that thematically-related decorative graphics increased recall of both literal details and deeper level themes embedded in text-- immediately after reading the text two weeks later.

Unfortunately, Mortensen & Schwartz (2009) found effects with a narrative passage that, because of its ambiguous nature, may have contributed to the influence of the graphics. They also failed to test the effects against a non-thematic graphic condition. This investigation focused on expository text-- more common in textbooks and media, and tested the graphics against a non-thematic graphic condition.

Methodology

Design

The design was a 4 Metaphorical Graphic Theme (Genocide vs. Civil War vs. Geographic Location vs. None) x 3 Passage Theme Type (Genocide vs. Civil War vs. Neutral) fixed ANOVA, with repeated measures on the passage theme variable.

Participants

Eighty undergraduate volunteers (mean age = 23) were randomly assigned to experimental conditions in equivalent proportions of gender.

Materials

Experimental passage. The experimental passage was an 839-word expository text describing the current conflict in Darfur, written to reveal two socio-political themes— civil war and genocide. Overall, the passage contained a total of 80 idea units—40 neutral, 20 civil war, and 20 genocide. Neutral idea units provided contextual background of the conflict, geographic information, and a historical timeline. Civil war idea units consisted of rebel groups uniting against a corrupt government for representation. Genocide idea units consisted of a planned extermination or removal of a group of individuals. To ensure idea units were properly assigned to their corresponding themes,

sentences were randomly ordered, rated by a group of 40 undergraduates, and factor analyzed for the identification of evoked themes and emotional valence. Outliers were removed, and the passage was reconstructed as a cohesive unit.

Experimental graphics. Three metaphorical graphics were designed. The first graphic was a topographical representation of the region. The graphic depicting Civil War graphic consisted of two lions of similar color and size engaged in combat. The graphic depicting Genocide consisted of two lions of similar color and size devouring a third lion of a dissimilar color and size. Graphics were normed by a separate group of 40 undergraduates to ensure they elucidated the intended metaphor without evoking the alternate metaphors. (See Figure 1).

Experimental Website. An experimental website was designed to display the materials. The website consisted of 15 hypermedia pages; informed consent, general instructions, an essay prompt, and a demographic questionnaire. Prior knowledge of the conflict was assessed by embedding a 7-point Likert scale into the demographic questionnaire.

Procedure

Participants navigated the experimental website with the experimental text presented on the right half of the screen while one of three graphics (or no graphic) were randomly presented on the left. Participants were allotted six and a half minutes to comprehend both the text and the graphic. Participants were then allotted 15 minutes to write an essay containing as much information as they could remember, including any thoughts, feelings, or reactions to the text.

Data Source

Measures of comprehension were derived by scoring the essays for the number of three types of idea units—passage-neutral material and material related to the genocide and civil war themes. Two graduate students scored half the protocols in each between-subject group, and redundantly scored 20% of the total. Inter-rater reliability was $r = .90$.

Findings

Neutral-passage idea units recalled were analyzed across Metaphorical Graphic Theme (Genocide, Civil War, Location, No graphic) in a univariate ANOVA. Results yielded a significant effect between graphic conditions, $F(3, 76) = 3.495$, $p = .02$. Post hoc Tukey tests revealed neutral passage recall was highest ($M = 6.4$, $SD = 3.68$) in the presence of the metaphorical graphic depicting the theme of genocide. By contrast, recall was significantly reduced when the graphics contained no metaphor for theme (location, $M = 3.65$, $SD = 2.65$), and no graphic at all ($M = 3.68$, $SD = 2.63$). No relation was found between prior knowledge of the conflict and number of idea units recalled. (See Figure 2).

Theoretical and educational significance

These findings support Mortensen & Schwartz (2009), revealing that thematically related graphics increase recall of both deeper level themes and literal details from text. The results support those found by Mortensen & Schwartz (2009), but underscore the presence of the effect with expository text and test it against a thematically unrelated and absent-graphic condition. It is important to note that Mortensen & Schwartz (2009) found the largest effects when learners returned two weeks after reading. Delay condition data and the extent to which recalled is mediated by critical thinking skills will be presented and explained using the model proposed by Schnotz and colleagues (2003).

PAPER PRESENTATION

What do players have to say about informal learning through games?

Ioanna Iacovides, The Open University, United Kingdom; James Aczel, The Open University, United Kingdom; Eileen Scanlon, OU, United Kingdom; Will Woods, The Open University, United Kingdom

It has been suggested that digital games can be powerful learning environments that encourage active and critical learning, including participation within "affinity groups" and "semiotic domains" (Gee, 2004). However, there is still a need to provide further empirical evidence to substantiate these claims, especially if educators want to try to replicate people's enthusiasm for games within a formal educational context. By addressing the question "How do players describe learning in the context of gaming?" this study seeks to further our understanding of how and what people learn informally through playing games by first examining the player perspective. A set of learning categories, based on a series of email interviews with a range of adult games players, is identified along with some themes to consider in relation to players' views on learning within this context. The findings indicate the importance of considering more than just what occurs during play, because, for example, players often consult external resources for advice about what to do in the game world. It is also pertinent to note players' ideas about value and transfer of learning across

contexts. The research raises questions about the completeness and applicability of these learning categories, and about how these categories relate to motivations for playing games and engagement during play.

PAPER PRESENTATIONS

Aligning Instruction to Individual Learning Needs in Adaptive Hypertext Learning Environments

Eniko Bezdan, Open University, Netherlands; Liesbeth Kester, Open University of the Netherlands, Netherlands; Paul A. Kirschner, Open Universiteit, Netherlands

Educational hypertext research on the effectiveness of pre-structured, static hypertext learning environments have greatly enhanced our understanding of how pre-structured hypertext environments affect navigation and learning outcomes. In particular, the effect of different types of graphic organizers have been extensively studied in the past two decades. In the meantime, however, the focus of hypertext and hypermedia design have moved on toward the development of ever more sophisticated adaptive techniques, yet empirical data about the cognitive effects of adaptive hypertext/hypermedia have been slow coming. The scarcity of research regarding the cognitive consequences of adaptive hypertext/hypermedia is somewhat surprising, as it has the potential to bring one of the longest standing ambitions in education one step closer: being able to provide instruction which is finely tuned to the learning needs of the individual learner. Knowledge accumulated about the learning effects of static hypertext environments, along with the results of studies about learner versus system control for task selection are examined, in order to outline possible future directions for adaptive hypertext/hypermedia research in an educational context.

When speaking of hypertext/hypermedia, the most basic kind of classification that can be made is between static and dynamic/adaptive. In static, more traditional, hypertext the sequencing of hyperlinks is fixed and the text content of the nodes remains unchanged. As the degree of interconnectedness via hyperlinks and the placement of hyperlinks between nodes determine the structure of hypertext (e.g., linear, hierarchical, network/semantic), navigation aids called spatial maps, graphical browsers or graphical organizers, depicting this structure of hyperlinks and nodes, are frequently used as a way of tackling the problem of disorientation (McDonald & Stevenson, 1998). Not surprisingly, one of the main themes of hypertext research in an educational context has been to examine the effects of different types of graphic organizers and its effects on navigation and learning outcomes (DeStefano & LeFevre, 2007).

Besides differences regarding their structure (e.g. linear, hierarchical, network), graphical organizers can also be divided into interactive and static. In the case of interactive organizers, the hypertext structure as defined by its hyperlinks, and the structure depicted in a graphic organizer need not be the same, as indeed they often are not. This is for example the case when nodes can be accessed directly by clicking on the concepts in the organizer. Once arrived at a textual node, there is only the option clicking on the back-button which leads back to the graphical organizer (e.g., Amadiou et al., 2009; Potelle & Rouet, 2003). Thus, a graphical organizer of this sort is not intended to describe the structure of the hypertext itself, as the lines drawn between the concepts in the graphical organizer do not correspond with the actual hyperlinks of the document. Consequently, it is almost certainly not the act of navigation (i.e. navigation here simply means clicking on concept in the organizer) which enhances learning, but the repeated viewing a representation of the relationships between the important concepts and of a knowledge domain.

Although in appearance similar to the interactive organizers described above, static graphic organizers usually have a different function. Static organizers can be a way of depicting the exact hyperlink structure of the hypertext document, as was the case in the study conducted by McDonald & Stevenson (1998). By visualising all possible pathways through the document, graphic organizers of this kind are navigation aids which could be said to convey a certain kind of spatial information. Thus, these are spatial maps which show how to get from a one text node to another, as well as the relative distance of textual nodes to each other as defined by the number intermediate steps

between them. What still remains unclear is, however, to what extent graphic organizers showing possible navigation paths engage same cognitive processes as graphic organisers in which the linkages (i.e. lines between concepts) do not correspond with the actual hyperlinks in the document. Besides the open questions remaining with regard to static hypertext, the cognitive effects of more complex, adaptive hypertext are largely unexplored. Today's learners encounter adaptivity on a daily bases when they for example use a search engine to browse the internet. Search engines make use of sophisticated algorithms analysing individual search histories in real time to select the hits in response of a search query, thereby adapting content presentation to the individual user. Yet, the widespread exposure to adaptive hypertext and hypermedia of the student population has so far sparked surprisingly little interest in educational research. Usability and user satisfaction studies are being carried out by the developers of adaptive hypertext/hypermedia, who come for the most part from the field of information and computers sciences. However, very little attention is paid in these studies to cognitive effects and learning outcomes (Brusilovsky, 2003).

The cognitive effects of adaptivity are being studied, however, in the specific context of adaptive task selection. Adaptations on task selection often focus on the degree of freedom the learner gets over task selection. The most common classification regarding the locus of control for the adaptations distinguishes between system controlled adaptation, user controlled adaptation, and shared control by the system and the learner (Corbalan, Kester, & Van Merriënboer, 2009). It could be argued that studies focusing on adaptive task selection, although mostly presented in hypertext/hypermedia format, are not representative of the hypertext/hypermedia that are typically encountered when browsing the web. Nevertheless, insights gained from these studies are still relevant for hypertext/hypermedia in a broader sense, as different levels of system and learner control can be incorporated and made adaptable in diverse hypertext/hypermedia formats. Utilising effectively the possibilities of adaptive hypertext and hypermedia could be the key to truly customising instruction to individual learning needs. But in order to do so, it is necessary to gain a better understanding about the extent the structural characteristics of navigation aids (e.g., graphic organizers) and hypertext structure as defined by its hyperlinks have differential effects on cognitive processes in the course of learning. Additionally, varying the locus of control in adaptive task selection is a good starting point to explore how shifting the control from the system to the learner and vice versa affects learning outcomes. There is also still much to be learnt about the possible objects of adaptive control, as the structure, content and the form and type of navigation aids in hypertext/hypermedia can all be made adaptable in a great number of ways. The focus of this paper is, therefore, to explore how adaptations regarding structure, content and navigability might interact with variations in the locus of control of these adaptations.

Effects of Drawing and Diagram Selection on Learning from Multiple Representations in Biology

Carla Firetto, Pennsylvania State University, United States

Peggy Van Meter, The Pennsylvania State University, United States

Active processing of diagrams embedded in science text improves student learning. This study tests two manipulations intended to improve learners' processing of diagrams. All participants read a biology text that contained 25 diagrams. 7 of these 25 diagrams were removed in both active processing conditions. In the first of these, the Draw condition, participants constructed their own drawings to replace the missing diagrams. In the Select condition, participants selected the correct diagram from amongst a set of alternatives. These two conditions were compared to conditions in which participants studied the materials with all diagrams provided and a text only control. Learning outcomes were evaluated on a multiple-choice posttest that was divided into two subtests. One subtest tested knowledge that corresponded to content related to the 7 missing diagrams. The second subtest tested knowledge taken from other areas of the instructional material. Results show that participants who constructed drawings scored significantly higher on the correspondent subtest than did participants who studied either the text only or the text with the

provided diagrams. There were no differences between the selection condition and the provided diagram condition on this subtest nor were there differences between drawing and selection. On the subtest with non-correspondent items, all three conditions that received diagrams scored significantly higher than did participants in the text only condition. There were no differences found between these three conditions on this non-correspondent subtest, however.

Student-generated drawing is a strategy in which learners draw to depict instructional text (Van Meter & Garner, 2005). Although this strategy has been shown to increase learning (Van Meter, Aleksic, Schwartz, & Garner, 2006), other studies have failed to show strategy benefits (Leutner, Leopold, & Sumfleth, 2009). This study tests the drawing strategy by comparing learning outcomes for students who draw to those who were either provided diagrams or were forced to actively process provided diagrams. Forced processing was operationalized by requiring participants to select a correct diagram from amongst alternatives (Zhang & Linn, 2010).

Research hypotheses include:

Participants who actively process diagrams will acquire more knowledge than will participants who do not actively process diagrams.

Participants who construct drawings will acquire more knowledge than will participants who select diagrams.

The benefits of active diagram processing will be found on subtests that assess both correspondent and non-correspondent knowledge.

High prior knowledge participants will benefit from active processing of diagrams to a greater degree than will participants with lower prior knowledge.

Methods

Participants and Design

106 Educational Psychology students were randomly assigned to conditions. Conditions were text only (Text), text and provided diagrams (Provided), selection (Select), and drawing (Draw).

Materials

Instructional Materials. Participants studied a paper booklet describing muscle physiology. The text contained 1,780 words and 25 diagrams. Diagrams either depicted structures or were sequenced to depict processes.

Condition Manipulations. Participants in the Text condition studied booklets containing only text. In the Provided condition, booklets contained text and all diagrams were provided. Participants in the Select condition received booklets in which seven diagrams were removed. At these locations, participants selected the correct diagram from amongst a set of alternative diagrams. Missing diagrams were dispersed throughout the instructional material. Participants in the Draw condition also received booklets with missing diagrams. Booklets in this condition contained blank space and participants drew a diagram depicting the contents of the accompanying text.

Pretest and Posttest Measures.

Participants completed a pretest assessing prior biology knowledge.

The posttest was a multiple-choice test. This test was divided into two subtests. The first tested knowledge corresponding to the content that participants either selected or drew. The second tested knowledge taken from other areas of the instructional material. There were 17 correspondent items (C) and 25 non-correspondent items (NC). The alpha coefficient for the full test was .77.

Procedures.

Participants completed experimental sessions in a computer lab. Sessions were randomly assigned to condition. The experimenter explained instructions for each condition. Participants in the Select and Draw conditions were told of the missing diagrams and of the selection or drawing task, respectively. Participants completed the demographic survey, pretest, and posttest online; instructional materials were on paper.

Results

An extreme-groups split on the prior knowledge variable divided participants into high and low prior knowledge groups. 91 participants remained following this split.

Condition effects on the posttest variables were tested in a 2 (prior knowledge) X 4 (condition) MANOVA. The interaction between prior knowledge and condition was nonsignificant. Main effects for both prior knowledge and condition were significant; $F = 7.36$, $p < .05$; $F = 6.16$, $p < .05$, respectively. Univariate tests revealed a

significant main effect of prior knowledge for both NC and C subtests; $F = 11.09$, $p \leq .05$, $F = 10.52$, $p \leq .05$, $F = 10.23$, $p \leq .05$. High knowledge participants scored higher on both subtests than did low knowledge participants. There was also a significant main effect of condition found for both NC and C items; $F = 5.84$, $p \leq .05$; $F = 10.23$, $p \leq .05$. Tukey's HSD comparisons revealed that the pattern of these effects differed across the two subtests. For the NC subtest, the Provided, Select, and Draw groups all scored significantly higher than did the Text group. There were no significant differences across any of the three groups that received diagrams along with text. On the C subtest, each group that received diagrams again obtained higher scores than did participants in the Text condition. There were also differences amongst these three groups. The difference between Select and Draw was not significant, but students who drew did score significantly higher than participants in either the Text or Provided conditions. Participants in the Select condition did not obtain significantly higher C scores than did participants in the Provided condition.

Discussion

This study demonstrated that the drawing strategy can be effectively embedded into lengthy instructional materials. Participants in the Draw condition were required to construct 7 of the 25 total diagrams. We believe that the construction of some, but not all, diagrams was important to the success of the strategy. First, the diagrams that were available to Draw participants provided a necessary form of support (Van Meter & Garner, 2005) by illustrating key structures and spatial relations. Second, providing some diagrams may have reduced the cognitive load associated with the drawing strategy (cf. Leuntner et al., 2009). The differential pattern of performance on NC and C items suggests that the benefits of drawing are local. Drawing did show an advantage when the subtest assessed knowledge directly related to drawn content. When non-correspondent knowledge was tested, however, Draw participants did not obtain higher scores than did Provided participants.

This study also demonstrated that active processing of the diagrams alone, through the selection task, did not improve learning (Van Meter et al., 2006). It is possible, however, that the selection task was not sufficiently complex to support learning (Zhang & Linn, 2010).

We are currently analyzing qualitative characteristics of constructed drawings. Once this coding is complete, we will examine relationships between these characteristics and learning outcomes.

PAPER PRESENTATION

The role of teacher characteristics in promoting student engagement

Jolien van Uden, ROC van Twente/ Twente University, Netherlands; Henk Ritzen, Applied University Edith Stein, Netherlands; Jules Pieters, University of Twente, Netherlands

In this research the relationship between teacher characteristics, like their motives to become a teacher, their self-efficacy beliefs, competences and interpersonal teaching style, are examined in relation with student engagement. Disengagement is an important risk factor in the process of dropping out. Three types of engagement are being distinguished: behavioural, emotional and cognitive engagement. The relation between all three types of student engagement, and teacher characteristics are explored during a survey in vocational education and training centres in the Netherlands (VET Colleges). This survey consists of a teacher and a student questionnaire. The results of both questionnaires will be combined, so the engagement of the students can be linked to the characteristics of their teachers. The first student results show a relation between student engagement and interpersonal teaching styles. The results of the complete datasets are examined during the spring and will be presented at the Earli 14th Bienial Conference.

Theoretical framework Student drop-out is a hot item in the Netherlands (Researchcentrum voor Onderwijs en Arbeidsmarkt, 2009). From a pedagogical perspective drop-out is the result of a long term process of disengagement and withdrawal of a student from education. This process of disengagement starts during the early years of education (pre-school and primary education) and could result in dropping out of school in higher and vocational education (Dynarski, Clarke, Cobb, Finn, Rumberger & Smink, 2008; Hammond, Linton, Smink & Drew, 2007). Drop-out is not the result of one single factor, research confirms that different factors influence the decision to drop-out. These risk-factors are interrelated, interact with each other and have a cumulative effect on the decision to quit school (Dynarski et al, 2008). Among the important factors that influence drop-out of school is student engagement (Appleton, Christenson & Furlong, 2008; Fredricks, Blumenfeld & Paris, 2004). The expectation is that if student engagement has increased and other risk factors are offset by prevention activities or special student care programs like mentoring and individual coaching programs, the drop-out rate will decline. In this research we focus on what the teacher can do to improve student engagement. The concept of engagement is a multidimensional construct consisting of three components (Appleton et al., 2008, p.370):-

Behavioral engagement: a student is behavioral engaged if he participates in the lesson. The student is on time, concentrates on the assignments given, puts effort into these assignments and undertakes action if possible.- Emotional engagement: a student is emotional engaged if he is enthusiastic about school. He is interested in going to school, he can identify himself with school and demonstrates a positive learning attitude. –

Cognitive engagement: a student is cognitive engaged if he understands the importance of his education. He is able to formulate his own learning goals, disposes of self-regulating abilities and the extent to which he wants to put effort in receiving good learning results. According to Hattie (2003) the teacher accounts for 30 percent of the variance in the school success of students. The abilities of the student himself account for 50 percent of the variance. Other aspects, family, school and peers, explain five till ten percent of the variance. If school success is explained for 30 percent by the role of the teacher, could that mean that the teacher would have the same impact on student engagement? A lot of research has been conducted to examine the relationship between drop-out and engagement (e.g. Archambault, Janosz, Fallu & Pagani, 2009; Finn, 1989; Klem & Connell, 2004) while almost no research has been done to examine the way teachers can influence the engagement of students. In this research we examine what teachers can do to improve the engagement of students in lower educational tracks (assistant training level 1 and basic vocational training level 2). In this inquiry the teacher characteristics are limited to: The motives to become a teacher: A person can choose to become a teacher based on extrinsic, intrinsic or altruistic motives (e.g. Pop & Turner, 2009; Richardson & Watt, 2006). Which motives are important in stimulating student engagement? Competences: Teachers can develop three types of knowledge and competences: subject knowledge, didactical knowledge and pedagogical knowledge (e.g. Beijaard, Verloop & Vermunt, 2000; Borko, 2004; Darling-Hammond & Bransford, 2005). Which competences are related to higher student engagement of students in vocational education level 1 and 2? Personal characteristics: Literature suggests that students in the lower educational tracks are in need of social-emotional competent teachers. Interested, warm and careful teachers can make the difference in case of students at risk of dropping out (Jennings & Greenberg, 2008; Pianta & Allen, 2008).

A large amount of self-efficacy is related to educational innovation, good class management, offering suitable learning activities and taking responsibilities for students in need of special care. Furthermore teacher self-efficacy is associated with student's motivation and self-esteem and more positive attitudes towards school (Caprara, Barbaranelli, Steca & Malone, 2006). The motives to become a teacher, the competences and personal characteristics will probably result in specific behaviour in the class in interaction with the students. Wubbels, Créêton and Hooyman (1985) have adapted the 'Rose of Leary' for educational interaction. They call this adapted model 'Model for interpersonal behaviour' (MITB). This model distinguishes two dimensions: the amount of influence and the amount of proximity. A higher score on both dimensions correlates with better cognitive and affective results (e.g. Den Brok, Brekelmans & Wubbels, 2006; Van Petegem, Aelterman, Van Keer & Rosseel, 2008). We examine whether these results also apply for student engagement.

Research design

In this research we examine which teacher characteristics influence student engagement. Little research is done with respect to this subject, therefore we decided to start an explorative survey. This survey consists of two questionnaires, one for teachers and one for students. The student questionnaire is used to measure the student engagement (all three components) and will be correlated with the results of the teachers. We ask the teachers and students to fill in a short version of the questionnaire on teacher interaction (QTI) (Wubbels, Créêton & Hooyman, 1985). Besides the QTI teachers answer questions about their motives, competences and the mentioned personal characteristics. All teacher questionnaires will be linked to the results of their students. One completed teacher questionnaire needs at least ten completed student questionnaires to be included in the analysis. Results Several institutions of vocational education participate in the survey at this moment. The first student results (N = 370) show a relation between student engagement and the interpersonal teacher style (table 1). In the beginning of 2011 we will be able to analyze the teacher questionnaires in combination with the student questionnaires. We will present the results of those analyses at the Earli Conference in Exeter and answer the question which teacher motives, competences and personal characteristics.

PAPER PRESENTATION

Science and technology education for the future: needs of future employees
Professional Development, Science Education, Vocational education

Liesbeth Baartman, Eindhoven University of Technology, Netherlands

Koeno Gravemeijer, Eindhoven School of Education, Netherlands

Technological developments and computerisation influence many jobs. The goal of this study is to identify to what extent employees need an increased and/or different understanding of science and technology to function in their jobs than is currently taught in schools. Whereas previous research tended to focus on very general skills (e.g., problem solving, communication) or long detailed lists of content knowledge, the focus of this study is on competences such as modelling and visualising. Companies most influenced by technological developments were selected in cooperation with National Centres of Expertise on vocational education. They were asked in which companies (1) more and/or different scientific and technological competences, and (2) creativity and flexibility are required. We focused on jobs at the level of senior secondary vocational education, as these jobs are most prone to being outsourced or taken over by computers. Employees working in the different companies were asked what knowledge and skills they use during their work, for example when working with machines and computers. Preliminary results show the influence of technological developments on almost all jobs. Required knowledge and skills are for example: data-analysis, the use of graphs and thinking beyond one's own job. The need for flexibility, creativity and insight in 'black boxes' seems to depend on the level of education.

Theory and aims The increased use of information- and communication technology and the influence of scientific and technological developments have caused many countries to redefine the key competences for adequately functioning professionals. This study specifically focuses on the needs of future employees: what competences in the domains of science and technology do they need to function adequately in their jobs, now and the future? Previous studies tend to focus on very general skills such as problem solving and communication (e.g., Holbrook & Rannikmae, 2007), which do not provide any specification of what should be taught. Other studies provide long and detailed lists of content to be taught in schools (e.g., AAAS, 1993). These lists run the risk of quickly becoming outdated as the amount of technical information is doubling every two years (Binkley et al., 2010). This begs the question whether we can identify competences that are general in the sense that we may expect them to stay valuable for a long time, but at the same time not too general to offer directions for curricula. This study tries to answer this question by interviewing employees in companies that are subject to technological developments. In the literature, two domains provide input to this study. First, a number of studies focus on 21st century-skills, lifelong learning competences, or key skills. For example, Binkley et al. (2010) analysed curriculum and assessment frameworks around the world, and identified ten competences, including creativity, critical thinking and ICT literacy. Voogt and Pareja-Roblin (2010) and Dede (2009) reviewed different reports about 21st century skills, generally relying on private/business initiatives. These reports mention skills such as communication, ICT literacy, social awareness, and creativity. Problematic is, however, that explicit links to educational levels are missing and the educational community hardly participates in this debate. These reports thus provide little direction with regard to the content of education. Second, we reviewed the literature about knowledge and skills used in the workplace. Here, hardly any studies exist on the use of science and technology at the workplace. There are, however, studies on mathematics that are general enough to be useful for science and technology as well (e.g., Bakker et al., 2006; Pozzi et al., 1998). These studies show the importance of: (1) knowing what processes are 'hidden' in computers or machines, and (2) analysing relationships between variables, based on quantitative data.

Data and Methods **Participants** The context of this study was vocational education in the Netherlands, preparing students for a job at levels ranging from assistant worker to middle management. This middle-level job was chosen, as it is likely to be most affected by technological changes, while employees are not specifically educated in this domain (Levi & Murnane, 2005). To identify companies most influenced by technological developments, interviews were conducted with National Centres of Expertise, who develop national qualification profiles for the different branches. Six interviews were conducted with representatives from: animal and plant care, car mechanics, audician/optician, graphical design, commercials/presentation, and nursing/care. Seven interviews were conducted with employees of these branches: a farmer using robots, employees of Ford cards, a company developing logistical systems, an ICT desk, an outsourcing company, and an audician. In November/December 2010, more interviews will be conducted in different branches, and nursing specifically. **Interviews** Representatives of the branches were asked to describe developments with regard to: (1) the amount of science and technology, (2) the content of science and technology, and (3) flexibility and creativity needed to function on the job. Depending on their function, the employees were asked:- what kind of machines and computer programs they work with;- if they need to know the 'invisible processes' inside;- how they are trained to work with new machines and computers;- what they do in case of an unexpected outcome or problem. All participants were asked to describe job situations in which scientific and technological knowledge and skills are used. Preliminary results

Full results, including the remaining interviews and more examples from concrete job situations, are presented at the conference.

Required knowledge and skills: most employees need some basic knowledge of science and technology. For example, audicians need knowledge of the auditory organs.

Flexibility and creativity: at lower levels, employees are not expected to suggest improvements or solve non-standard problems. An exception is 'defence/tank' mechanics. They need to know the exact working of tank engines, enabling creativity in emergencies.

Insight in black boxes: opinions seem to differ here. In general, employees can work with machines without knowing 'what is going on inside'. For example, graphical designer can use software to make sketches without knowing how colours mix. Theoretical and educational

significance Most jobs seem to be influenced by computerisation and technology, leading to changed requirements in terms of knowledge and skills, creativity and insight in black boxes. The identification of these changed requirements could guide curriculum adaptations, better preparing young people for their future jobs. More research seems warranted on the use of science and technology at the workplace (following studies on mathematics). This study is a first step in this direction.

Using a Personal Development Plan for different purposes and its influence on learning & performance
Assessment methods, Assessment of Competence, Professional Development

Simon Beusaert, Maastricht University, Netherlands

Mien Segers, Maastricht University, Netherlands

Wim Gijssels, Maastricht University, Netherlands

Today, organizations are increasingly implementing assessment tools such as Personal Development Plans. Although the true power of the tool lies in supporting the employee's continuing professional development, organizations implement the tool for various different purposes, professional development purposes on the one hand and certification/selection/accountability purposes on the other (Smith & Tillema, 2001). The study presented here aims at a better understanding of how the purpose of the Personal Development Plan (PDP), as perceived by the employee, influences the extent to which s/he undertakes learning activities and consequently leads to improved performance. Data were collected from 286 employees working in a regional Dutch tax office and 81 experts from an international organization that is specialized in medical technology (n=367). Data were analyzed by conducting hierarchical regression analyses. Results indicate that perceiving the PDP either as a learning and development tool or as a certification and selection tool, positively predicts the undertaking of learning activities and the employee's performance. Follow-up regression analysis indicated that the most powerful predictor of undertaking learning activities and a high-quality performance is the extent to which employees perceive PDPs as serving learning and development purposes. The results of this study suggest that if an organization wants their employees to learn by undertaking learning activities and in turn perform better, the tool should in the first place be introduced and used as a learning and development tool.

1. Aim Today, organizations are increasingly implementing assessment tools such as Personal Development Plans (PDPs) to stimulate employees to intentionally undertake learning activities and in turn improve workplace performance (London, 1997; van de Wiel, Szegedi, & Weggeman, 2004). In general a PDP can be described as an assessment tool embedded in a larger assessment cycle of development and performance interviews; used to gather and document information about the competencies the employee worked on and is planning to further develop (Beusaert et al., 2010). It is argued that although there is a trend towards using the tool for performance appraisal (summative assessment), the power of the tool lies in supporting employees' professional development (formative assessment) (Darling-Hammond & Snyder, 2000; Smith & Tillema, 2003). Some authors even wonder whether a single assessment format such as a PDP can serve different purposes at the same time (Dochy & McDowell, 1997; Wolf & Dietz, 1998). For example, different authors question whether PDPs can be discussed in development interviews as well as in appraisal interviews, conducted by one and the same supervisor (e.g. Beck, Livne & Bear, 2005; Wolf & Dietz, 1998). When using the tool for both purposes at the same time, the purpose of the tool as well as the guidelines and the structure are not always clear (Smith & Tillema, 2003). In this respect, it is argued that one of the quality standards of assessment is making the purpose of the assessment clear (e.g. Tillema, 2003), especially in the case of PDPs because of the potential differences in content of and approach to the tool (Arter & Spandel, 1991). When it is not clear what the PDP strives toward, this jeopardizes the quality of the assessment practice. Employees' self-protection and fear of underachieving may lead to the collection of unauthentic evidence and the construction of

invalid PDPs, instead of PDPs that openly reflect on the employee's learning and development (Smith & Tillema, 1998, 2001). On the contrary, other authors believe that information gathered during the learning or development process can be very useful for summative evaluation (e.g. Snyder, Pippincott & Bower, 1998). Despite the many arguments elaborated upon in literature, there is hardly any evidence on the effect of implementing PDPs for different purposes. The study presented here aims to contribute to a better understanding of how the purpose of the PDP, as perceived by the employee, influences the extent to which s/he undertakes learning activities and in turn, leads to improved performance. Based on the aforementioned literature, the following hypotheses are formulated: H1. Perceiving the PDP as a (organizational and individual) learning and development tool predicts the employee's undertaking of learning activities and the employee's performance significantly positive. H2. Perceiving the PDP as a selection and certification tool predicts neither the employee's undertaking of learning activities, nor the employee's performance significantly positive. H3. In the case both learning/development and certification/selection goals are taken into account, perceiving the PDP as a learning and development tool is the most powerful predictor of the employee's undertaking of learning activities.

2. Method Two organizations participated in the research. Participants are 286 employees (response rate 20%) of a regional Dutch tax office and 81 employees (response rate of 41%) from an international organization that is specialized in medical technology. For an overview of the different measures, example items, and Cronbach's alphas, we refer to Table 1. Data analysis was done by calculating descriptives and conducting correlational and regression analyses. Table 1 Overview of the different scales and their descriptives

Scale	N	Alpha	Example items
The perceived nature of the goals			Indicate on a Likert scale going from 1 to 5 in which way your organization is striving for the following goals by implementing PDPs:
Personal learning and development goals	3.89		Stimulate reflection or learning.
Organizational learning and development goals	4.88		Stimulating collaboration with colleagues.
Certification and selection goals	4.76		To delivering evidence to my supervisor.
Outcome variables			
Undertaking learning activities	6.90		Because of using a PDP I look up things in books, journal or on the internet.
Performance	6.97		Since I am using a PDP and have related meetings, the quality of my work improved.

3. Findings The correlational analysis indicate that the three different goal components correlate significantly positive with Undertaking learning activities and Performance. To examine the independent effect of the three perceived goals components on the employee's undertaking of learning activities and performance, three hierarchical regression analyses were executed. The findings indicate that personal as well as organizational learning and development goals predict the employee's undertaking of learning activities ($b = .18$; $p = .02$; $p < .05$) and performance ($b = .35$; $p = .03$; $p < .05$) significantly positive, which confirm Hypothesis 1. In contrast to our expectations, the Certification and selection goals also predict the undertaking of learning activities ($b = .14$; $p = .04$; $p < .05$) and the employee's performance ($b = .29$; $p = .01$; $p < .05$) significantly positive, which is not in line with Hypothesis 2. However, in order to determine which goal component is the most powerful predictor of the employee's undertaking of learning activities and performance, we conducted subsequently hierarchical regression analyses. The results show that organizational learning and development goals is the most powerful predictor of undertaking learning activities ($b = .14$; $p = .04$; $p < .05$). Next, the performance of an employee is more likely to improve because of the PDP if s/he perceives the assessment tool as a learning and development tool (personal: $b = .17$; $p = .03$; $p < .05$) and not as a certification and selection tool (not significant).

4. Theoretical and educational significance of the research Theoretical significance. To our understanding this is the first quantitative study that researches the influences of the different perceived purposes of the PDP on the undertaking learning activities and performance in an organizational context.

Practical significance. This study has implications for human resource development in organizations. First, in order to stimulate employees to undertake learning activities and improve their performances by using a PDP, introducing and using the PDP as a tool for learning and development is the most effective. Second, this research leads to the question: How to balance between certification and selection purposes on the one hand and learning and development purposes on the other, knowing that learning and development purposes are stronger predictors of undertaking learning activities and performance? First, keep learning and development interviews separate from performance interviews and have them conducted by a different person. Second, make a distinction between the criteria used for discussing the PDP during the learning and development interviews and the criteria used during performance interviews.

Exploring new horizons: teacher professional development through networked learning
Continuing professional development in Teachers, Professional Development, Social interaction

Daniel Van Amersfoort, Open University, Netherlands

Monique Korenhof, Open University, Netherlands

Nienke Moolenaar, University of Twente, Netherlands

In educational practice and policy, teachers' professional development initiatives are catering to the notion that teacher learning is situated in a dynamic social context. One way in which teacher learning is shaped in practice is through networked learning. However, empirical evidence of networked learning as a means of teachers' professional development is scarce. The aim of the study was to examine teachers' perceptions of, and experiences with, networked learning to explore core concepts of teachers' networked learning in primary education. This article reports on an exploratory case study among primary school teachers of ten learning networks in two school districts in the Netherlands. We used constant comparative analysis in combination with an input-process-output approach to code the transcribed interviews on teachers' perceptions of networked learning. Findings indicated that teachers' perspectives on, and experiences with networked learning can be attributed to five main aspects referring to pre-conditions for networked learning (input), four main aspects related to the process of networked learning, and five main aspects pointing at output of teacher networked learning. Moreover, we found evidence of feedback loops connecting the input, process, and output stages. Insights from this study provide meaningful understanding of teachers' professional development through networked learning and the factors that constrain and support teachers' networked learning in daily practice. It is through these networked learning experiences that teachers' professional development will permeate teachers' daily practice and, ultimately, improve instructional practice.

PAPER PRESENTATION

Languaging and identities in the construction and organization of 'Swedish for immigrants'.

Jenny Rosen, University of Dalarna, University of Orebro, Sweden; Sangeeta Bagga-Gupta, University of Orebro, Sweden

This study draws upon ongoing research in Project-KIK, Categorization of Identities and Communication. Project-KIK is interested in social practices in a tailored education for adult immigrants in Sweden and the discourses framing it. The theoretical framework employed approaches language policies in terms of a dialectical relationship between the policies (macro level) and the learning that takes place in the language classroom (micro level). Our empirical material consists of audio- and video recordings of everyday interactions at an institutional arena constituted under the name of "Swedish for immigrants (Sfi)".

Our preliminary analyses illustrate among other issues, how multilingualism and monolingualism in Sweden are reflected in and negotiated through everyday interaction and the social practices in classroom settings. By highlighting empirical examples from two separate language learning classrooms, we discuss how different learning environments are created in relation to how teachers and students negotiate their understandings of languages and identities. The

understanding of Swedish as the principal and only language used for communication in this institutional setting is challenged by the multilingual languaging practices that the students employ. As a result, different opportunities for the students (both in terms of learning as well as constructing and negotiating identities), are constituted.

The study presented here draws upon the ongoing work in project-KIK, Categorization of Identities and Communication. Project-KIK is interested in both the social practices and the discourses that frame a tailored education for adult immigrants in Sweden. It focuses on conceptualizations and the "doing" of languages and identities in the specific institutionalized arena that emerged in the post-world war II period with the intention of teaching Swedish language to adult immigrants in the nation-state of Sweden.

Research concerned with the language situation of adult immigrants in different European national contexts is not uncommonly founded upon an understanding of languages in terms of being standardized, static and with defined (often national) boundaries. For example, there is an established body of literature that focuses on language policy and politics at the societal (or macro) level, with an emphasis on the legal rights and policies in different nation states. Our interest in languages lies in their dynamic and fluid nature and embraces the theoretical perspective found in dialogism (e.g., Linell 1998, 2009). This entails that our approach to language policies is both multidimensional and complex.

The theoretical framework employed in the study that is presented here approaches language policies in terms of a dialectical relationship between policy (macro level) and the learning that takes place in the language classroom (micro level). The study presented here explores how policies regarding languages are reflected in the organization of language learning for adults. More specifically, we focus upon issues of multilingualism and monolingualism and show how these are oriented towards in the mundane, everyday social practices in classroom settings. The Swedish Language Act from 2009, maintains that 'Swedish is the principal language in Sweden', and that 'all residents of Sweden are to be given the opportunity to learn, develop and use Swedish'. The Act furthermore decrees that persons with "a different mother tongue" are to be 'given the opportunity to develop and use their mother tongue'. The tension between Swedish as the principle language on the one hand, and a recognition of multilingualism on the other, and which is reflected in such central policy documents, comes also alive in the language learning classroom.

Using empirical examples from our ongoing study, we show how questions regarding the status of Swedish and multilingualism are not only issues of debate on a macro level, but are (i) reflected in and (ii) discussed by the members of the language learning classroom and (iii) shape languaging activities there. KIK-project encompasses approximately 85 hours of audio and video materials and ethnographic field notes from five different classroom settings at an institutional arena that is called "Swedish for immigrants (Sfi)". Members in the typical Sfi classroom include 10-20 adult immigrants with diverse linguistic experiences and cultural resources. A variety of monolingual Swedish language textual materials are used in these classroom settings. The diversity of the students in the classroom with regards to their educational and linguistic experiences is understood, in the specific institutional setting of 'Swedish for immigrants', as a challenge for the organization of learning and instruction. In this presentation, we juxtapose empirical examples from two different types of classrooms: in the first, the institutional categorization of the students is done in terms of "limited educational background". Most of these students have at the time of the field study been enrolled in the educational program for one semester. In the second classroom, the students are categorized in terms of "long educational background" and the students in the project classroom had been enrolled from a period of a couple of weeks to approximately one year.

Through our analyses, we discuss how different learning environments are created following how teachers and students negotiate their understandings of languages and identities in the classroom. The understanding of Swedish as the principal and only language used for communication in this institutional setting is contrasted with more multilingual languaging practices that the students employ. Our analysis raises issues regarding different types of opportunities for the learning of Swedish as well as the ways in which identities are constructed and negotiated in the two different settings. In an environment, in which students multilingual resources are acknowledged and seen as a tool in the institutional target language learning, students are also given the opportunity to constitute a multilingual identity in their new country of residence. In contrast, when the students' use of their linguistic resources is subverted, students use resources to challenge the "Swedish only norm", rather than focusing on the language learning. Empirical examples will be used to illustrate these tensions.

PAPER PRESENTATION

Teachers' Mutual Understanding - A Systematic Analysis of Talk with Two Approaches

Inger Osterlund, Abo Akademi University, Finland; Varpu Tissari, University of Helsinki, Finland

Mutual understanding among teachers has an impact on development of school and students' success. The present study highlights the complexity in dialogues which signify the use of different approaches when analysing the data. The aim is to analyse teachers' mutual understanding during meetings by using different methods of analysis. This micro educational study on social interaction, analyse video records from teacher meetings, which are part of the data from two larger case studies. The first case study examines the multi-professional cooperation of an elementary school teacher and a subject teacher whilst they are planning a field visit to a nature school. The second case study investigates changes of codes in the collegial talk of secondary school teachers at a formal teacher meeting. Theoretically, the selected excerpts are examined from the sociocultural theories of learning, and from the sociolinguistic perspective. Methodologically, the excerpts are scrutinized by analysis of communicative functions, and according to the multimodal analysis. The results from the multimodal analysis point out a few utterances to the situated meaning that are accepted but not heard, or tolerated. The analysis of communicative function provides further insight on the thematically different communicative functions embedded in the interaction of teachers participating at the meeting. The results provide a diversity that indicates how a systematic outlining of the data varies. Thus, the study may stimulate networking of teachers both in virtual and face-to-face interaction.

Mutual understanding among teachers and between teachers and other professionals cooperating has an impact on development of school and students' success (Little, 2010; 1990; Willman, 2001; Fullan, 2002; Hargreaves, 2003). The ways in which such mutual understanding is constructed during teachers' talk vary and depend on which entries are chosen to explore talk.

In this micro educational study on social interaction, the authors analyse video records the teacher meetings, which are part of the data examined in two larger case studies (Yin, 2003). The first case study examines the multi-professional cooperation of an elementary school teacher and a subject teacher whilst they are planning a field visit to a nature school, in which the latter is working as a nature school teacher. The second case study examines changes of codes (Bernstein, 1990; Bourdieu & Passeron, 1990; Goffman, 1981; Goffman, 2000; ; Grenfell & Kelly, 1999; Lemke, 2007; Moore, 2006; Schiffrin, Tannen, & Hamilton, 2001; Tannen, 1998; Tannen, 2005) in the collegial cooperation of secondary school teachers at a formal teacher meeting.

The aim is to explore and analyse the construction of mutual understanding of teachers participating in the meetings, by using different perspectives and analysis methods. The objectives are to examine the teachers' talk in order to understand how teachers orchestrate their interaction with each other, and to analyse the obstacles and opportunities in such situations.

A sequence of the video data from both of the case studies is analysed by exploring the interaction and talk of teachers. Theoretically, the selected excerpts from the data from both case studies are examined from two perspectives. The first perspective draws on the sociocultural theories of learning (Packer & Goicoechea, 2000), and the second perspective draws on the sociolinguistic perspective using Bourdieu (Bourdieu & Nice, 1986) and with an interactional input from Gumperz (Schiffrin, 1994; Schiffrin, Tannen, & Hamilton, 2001) through Tannen (1989; 1998; 2005).

Methodologically, the excerpts from the data from both of the case studies are scrutinized by the analysis of communicative functions, and according to the multimodal analysis. The former sheds light on the thematic nature of interaction, and also on its moment-by-moment construction in the ongoing interactions (Kumpulainen & Wray, 2002; Kovalainen & Kumpulainen, 2005; Kovalainen, & Kumpulainen, 2007). The latter refers to the problematic in breaking up interaction into separate modes. This problem is overcome by looking at all the modes together at the same time, and examining how the modes interact in a small scale of data for a later exploration in the larger scale of data. (Jewitt, 2009; Bezemer & Jewitt 2010.)

The research questions are the following: 1. How mutual understanding is constructed during teachers' talk? 2. What may be the obstacles and opportunities for analyzing the talk with different methods of analysis?

The preliminary results from the multimodal analysis point out that the informing part of the meetings is dominating. However, when teachers' talk is addressed and when they form spaces for negotiations with arguments, the mutual understanding is shaped by cultural codes and quick changes of codes. A few utterances are left unnoticed which draws attention to the situated meaning as accepted but not heard, or as tolerated. The communicative functions provide insight on the thematically different communicative functions embedded in the interaction of teachers participating at the meeting. Both analysis methods are influenced by the debate of social relations in communicative practices that are in nature more for bringing in positive than negative influences.

Firstly, the results relate to the social capital and trustful networks within heterogeneous groups where both weak and strong ties (Coleman, 1990) are essential for mutual understanding. Secondly, non-verbal communication influence in the negotiations (Auer & Di Luzio, 1992; Duranti & Goodwin, 1992; Mercer, 2000; Tannen, 1989; Norris, 2004), and in the effort of finding a solution that is accepted or at least tolerated by the members (Firth, 1995; Naquin & Kurtzberg, 2009). Though the dialogues and utterances in the examples are chosen to explain the main objective of mutual awareness, it is impossible to generalize. Every speech event and utterance is strongly attached to the spatial and the contextual settings that are unique and will never occur again.

As a conclusion, the results of the analysis from different perspectives provide a diversity of systematically outlining the data. Therefore, the potential of teachers' talk and social interaction highlight differences either in the cultural sense, as different cultural codes, or in the subject, as differences in ontology and epistemology, even if the focus is the same. It is of significance to go beyond oneself, and extend the understanding even if the mutual understanding is not reached but only tolerated. Finally, the analysis in this study highlights the complexity in dialogues and multipart talk which signify the importance of the different approaches and data.

The paper argues for the essential to approach a problem, which is multifaceted, from different standpoints. The key elements (namely, talk, artefacts, gazes, gestures, etc.) in critical situations are paving the way to move forward. Therefore, the data is analysed first in a small scale, and later on in a large scale. Finally, the paper focuses on the critical situations in talk that may change overtime and space, to stimulate cooperation and networking of teachers both in virtual and face-to-face interaction.

PAPER PRESENTATION

"What's a Fourth? What's a Fifth? What's the Point?": Constructing Definitions in Scientific Inquiry

Leslie Atkins, California State University, Chico, United States; Irene Salter, CSU, Chico, United States

In a class for preservice teachers, undergraduate students observed and attempted to explain complex phenomena related to light and color. In doing so, they frequently invented terms which were negotiated and refined by the class, and some became precise, stable, and useful terminology. These include invented terms (e.g., "the seconds" and "kooshing") and everyday terms (e.g., "focus"). In this paper we provide an analysis of the evolution of one of these terms, "the seconds," and how demands of intersubjectivity, together with theory, observation, and utility, shape the evolution of the definition. In the analysis, we see not only improvements in students' understanding of light, but a shift towards academic discourse registers and a nuanced understanding of the role of definitions in science

Objectives

A debate regarding the definition of a "personal epistemology" recently appeared in the *Journal of the Learning Sciences* as Sandoval (2009) argued that clarity of definition is necessary for theoretical progress, while Elby (2009) countered that theoretical progress must precede the definition. "The scope of personal epistemology should not be decided entirely a priori," Elby claims, "it is more productive not to converge on a definition until further empirical and theoretical progress points us toward the best way to 'cut up [nature] ... along its natural joints'" (p. 64). We point this out not to make a statement regarding personal epistemology, but definitions. Many curricula take a "front end" approach: students are given precise definitions and they use these to enable progress on understanding key ideas. An alternative is an "iterative" approach: allow for students' inquiry to make theoretical and empirical progress before definitions reach scientific precision. There is little work, however, on how we might facilitate student inquiry to promote this iterative process, or even what such iteration might look like. The paper will describe the evolution of the definition ("the seconds") that undergraduate students constructed in a course on scientific inquiry, and addresses the question of how and why this term changes over time. We will argue that, through the communicative need to agree on a definition, theory and experiment are advanced, and students develop a shared understanding of characteristics of light, constructing a nuanced and scientific definition that balances pragmatic constraints with theoretical ideas.

Framework and methods

Two theoretical perspectives guide our interpretation of student ideas: idealized cognitive models and knowledge-in-pieces. Idealized cognitive models were introduced by Lakoff (1990), arguing that categories arise from cognitive models that carve out a space for terms. Such models vary in size and stability; they may be constructed on the fly (Barsalou 1983) and still maintain the structure characteristic of common categories. When analyzing student terminology and the stories that provide boundaries to those terms, we take a knowledge-in-pieces framework (diSessa 1988), interpreting utterances not as evidence of beliefs but stories constructed in the moment and sensitive to context. In approaching the question of how the terminology is shaped by student inquiry, we employ Interaction Analysis (Jordan and Henderson 1995) and recent work on intersubjectivity (Nathan, Eilam et al. 2007). Transcripts

are analyzed for evidence of repairs (Schegloff 1992), and how such repairs modify participants' initial descriptions. Data comes from a course, Scientific Inquiry, for undergraduate preservice elementary teachers. Every class session is videotaped, and digital copies of student work are kept, and our analysis focuses on identify events that cause shifts in terminology (here, the term is the "seconds").

Data

In the second week of the course, there are two competing ideas to explain the observation of "fuzziness" on the edge of a spot of light (Fig. 1): light "bends" around corners or "bounces" along walls. In a small-group conversation, Amanda terms these bounced rays "the seconds." The following day the whole class works to understand Amanda's idea. Below, we provide a few critical turns in the discussion of "the seconds" that foster evolution of the term.

4. Allie: [Fig. 2]...Whites are the firsts— they all get reflected...— pinks are the seconds... each time it hits a wall you add one, pretty simply.

5. Breanna: It's gonna get dimmer and dimmer...That's why we were talking about how it matters if it's a second or third or fourth. Because every time it hits something it's going to get dimmer. Other students disagree with their diagram and, by turn 30, students have noted several differences in their diagrams of "seconds," with one student (Dee) pressing for representational conventions. In time, her request is recast not as mere convention, and students identify empirical and theoretical work required to clarify the term:

31. Breanna: I don't think it matters what it hits off of as long as it hits off of something then it should be called a second. And if it hits something twice, it's a third...

40. Allie: ...the mirror makes a huge difference because the the mirror does not act like a wall. It reflects much differently. ...

52. Dee: So I guess the real question is: 'when it hits the mirror is any of the light absorbed.' Because to me the definition of a second is 'when it hits something, some of the light is absorbed so not all of it is coming back out.'

60. Steven: I think it's going to be extremely hard to differentiate what's a second, what's a third... what's the point? Might as well just break it down to 'primary light' and 'secondary light.' Like anything secondary and after will be obvious. ...We must have some agreement on definitions in order to communicate effectively, but the terminology must also agree with something useful - a 'carving at the joints' of things we wish to understand. Steven argues that distinguishing seconds from thirds is pointless for our activity: we can understand the "fuzzy edge" as being caused by light that bounced, regardless of how many times.

These interactions drive empirical investigations, which then inform the iterative development of the definition of the term, "the seconds." To create terminology, as Lakoff suggests, is to model: to construct a story that carves out relevant objects that are given names. The stories may be constructed on the fly, with terms that are provisional and contextual. These stories, however, have an audience, and the need to establish intersubjectivity with this audience drives the modification of stories; the group artifacts serve to drive stability of the stories, and, concomitantly, the terminology develops "hard edges." Over time, this interaction creates terminology that is increasingly stable, precise and clear.

This proposal highlights students' initial steps at constructing and refining terminology; a final paper will include a more complete story of the terminology that students ultimately constructed, the interplay of experiment and theory that, together with interactions, led to the final definition, and a more detailed description of methodology.

PAPER PRESENTATION

Newcomers' Learning in Communities of Practice

Julia Eberle, Ludwig-Maximilians-University Munich, Germany; Karsten Stegmann, University of Landau, Germany; Frank Fischer, Universität München, Germany

Learning in communities of practice is mainly informal without explicit learning goals. Newcomers start as peripheral members and become active members as their "community knowledge" grows. This process of newcomer's learning in communities of practice is only vaguely described as legitimate peripheral participation and hardly studied empirically. Thereby, it is hard for communities to support newcomers learning process: knowledge on effective means how to facilitate the integration of newcomers is lacking. Approaches from group research on socialisation tactics may fill the gap. Therefore, we investigated to what extent group size, time, and different socialisation tactics as an addition to the process of legitimate peripheral participation are related to the integration of newcomers in communities of practice. A correlation study on 16 German student associations with overall 223 members was conducted using social network surveys to measure the level of integration. In interviews with experienced community members, data about tactics to foster the integration of newcomers were collected. Five socialisation tactics could be identified. In a HLM analyses two of them (positive welcoming strategies and accessibility of knowledge) showed to be significantly related to the level of integration. In this model also group size was included, which was negatively related to the level of integration, while the factor time itself played no important role. Therefore, we assume that combining the concept of communities of practice and legitimate peripheral participation

with theories from group research is a promising approach for a better understanding of the learning process of newcomers in communities of practice.

Learning by working on a shared topic with a group of people, like on an open source software project, is mainly informal and explicit learning goals can hardly be defined. Groups of people who work together on a topic for some time have been conceptualised as communities of practice (CoP). Barab and Duffy (2000) define a CoP as an interdependent system that puts the individual into a larger context and provides meaning for being and acting, based on a common cultural and historical heritage of shared goals, understandings and practices among the members. Newcomers who are integrated in a CoP undergo a complex process of learning and enculturation that shapes their identity as an active member of a larger system. Lave and Wenger (1991) describe this process as legitimate peripheral participation (LPP), which seems mostly to be a matter of time that a newcomer spends in the CoP. However, this concept is so far not very well empirically investigated. Promising approaches to expand the understanding of the LPP process can be found in group research. Regarding socialisation of new employees in work groups, socialisation tactics have been found influential means (Saks, Uggerslev, & Fassina, 2006). Levine and Moreland (1991) collected important tactics, used by work groups to foster the socialization process of the newcomers; e.g. encapsulation describes activities in which older group members encourage newcomers to spend their time for the CoP and with its members. Positive welcoming strategies as another example are used, when groups try to welcome newcomers in a friendly way. In addition to this, group size has been shown to influence individual thinking and behaviour in (work) groups, e.g. voluntary turn-over rates (Hausknecht, Trevor, & Howard, 2009). This leads to the assumption that the size of a CoP could also influence integration processes of newcomers. So far it is unclear what factors structure, support or hinder the LPP process of newcomers in CoPs. We assume that the learning process is not only a matter of time, but that specific socialisation tactics are used by CoPs that shape this learning process.

Research Question

To what extent can group size, time, and the use of socialization tactics predict the integration of newcomers in CoPs? Method223 members of 16 student associations from the University of Munich participated in this study. They were chosen as an example for CoPs as they fulfil all three criteria defining a CoP mentioned above: they are an interdependent group with a shared cosmology and a reproduction cycle. The level of the members' integration in their CoP at a certain point in time was computed for every newcomer, based on data of a social network survey. In this survey all members were asked to indicate how intensively they had worked with each of the other members during the last three months. Additionally a semi-structured interview was conducted with an experienced senior member of every student association. In this interview participants were asked how their CoP had proceeded to integrate newcomers and were then asked about the socialisation tactics described by Levine and Moreland (1991). Via a content analysis a value for the use of the found integration mechanisms was then achieved for every CoP. An exploratory stepwise multi-level regression analysis (HLM) including the individual and the CoP level was applied to test the research question.

Results

Five socialisation tactics were found that the CoP members reported to use to foster the integration process of their newcomers: supporting legitimate peripheral participation, positive welcoming strategies, accessibility of community knowledge, encapsulation, and providing information about the CoP to potential newcomers before their entry. To explore which of those aspects are actually relevant to the process of newcomer integration the found tactics and the group size were step-wise included into a multi-level regression model which in the beginning only included time to predict the level of integration. In the final model the level of integration was negatively predicted by group size ($\beta = -0.139$) and positively predicted by positive welcoming strategies ($\beta = 0.716$). Time alone had no significant effect ($\beta = 0.025$), while it predicted the level of integration negatively in combination with positive welcoming strategies ($\beta = -0.118$) and positively in combination with accessibility of knowledge ($\beta = 0.047$). In short, newcomers are better integrated in smaller groups. They are integrated faster if the groups focus on knowledge access strategies. However, the explanation of the influence of welcoming strategies is more difficult: newcomers in groups that use this strategy are better integrated in general, but slower compared to groups that put less effort in positive welcoming strategies.

Conclusions

Our results provide evidence that combining the idea of LPP and theories from group research is a promising approach to a differentiated understanding of the underlying mechanisms of learning processes in CoPs. Five socialisation tactics have been identified in this study and for two of them a significant relation to the learning process in CoPs have been proved. This implies that it seems possible for community members to actively shape the learning process of newcomers and that not every tactic applied and widely used is really effective for learning.

Meta-cognition

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature

Robert Cantwell, University of Newcastle, Australia; Janene Budd, University of Newcastle, Australia, Australia;
Jill Scevak, University of Newcastle, Australia

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature Janene Budd, Jill Scevak, and Robert Cantwell University of Newcastle, Australia A growing body of research has documented the affective, or emotional, demands associated with PhD candidature, which may include coping with social isolation and the fear of negative evaluation by significant others, such as supervisors, peers, or family, and dealing with uncertainty and intellectual change. Unfortunately, there has been a lack of research attention regarding how these affective experiences are interpreted and managed at the level of the individual PhD student, and the impact of this on persevering with doctoral candidature. To explore this issue, the results from the first phase of a large scale, mixed-methods longitudinal study investigating the metacognitive and affective profiles of over 1200 PhD students from across Australia are presented, and complemented with the results of a small-scale qualitative study of PhD students who were experiencing a 'crisis of persistence', and considering termination of candidature. Together, these findings suggest that although an affective response to the personal changes associated with the transformational nature of higher level intellectual development may be expected in doctoral study, misinterpreting this affective experience can have potentially serious consequences in terms of perseverance with PhD candidature, ranging from unnecessary attrition to suicidal ideation. The results of the two studies will be discussed in terms of the implications for doctoral pedagogy. In particular, we discuss the importance of, and strategies for, helping students to more comprehensively understand and manage the affective experiences associated with doctoral learning, and identify areas requiring further research.

"I didn't expect to feel like this" – Affect management and perseverance in doctoral candidature Janene Budd, Jill Scevak, and Robert Cantwell University of Newcastle, Australia Various aspects of doctoral candidature have attracted much research attention since the recognition of the high attrition and slow completion rates that occur across institutions internationally. The background to this paper is the growing body of research documenting the affective, or emotional, demands associated with PhD candidature, which may include coping with social isolation and the fear of negative evaluation by significant others, such as supervisors, peers, or family, and dealing with uncertainty and intellectual change. Although it is generally agreed that intellectual development is expected to occur during the doctoral research process (e.g. Batchelor & Di Napoli, 2006; King & Kitchener, 2002), Stevens-Long and Barner (2006) have noted that the management of affective experiences accompanying intellectual development in higher education has been largely ignored in the literature. More importantly, there is a lack of understanding of how these affective experiences are interpreted and managed at the level of the individual PhD student, and the impact of this on progressing through doctoral candidature. To address this issue, an ongoing, large-scale, mixed-methods design study is investigating the affective and metacognitive profiles of over 1200 PhD students from universities across Australia, to provide both cross-sectional and longitudinal data regarding the management of affect during candidature. The study is underpinned by a constructivist learning theory framework, and assumes that there will be individual differences in the application or experience of a variety of metacognitive, affective, and personality factors as students seek to manage the intellectual and other demands of doctoral learning.

The study consists of three components: 1) comprehensive online surveys assessing metacognition, affect and personality, along with demographic and candidature data, conducted at baseline and with a 12 month follow-up, 2) brief online 'journey tracking' surveys conducted monthly for 12 months, and 3) two series of telephone or email interviews. The focus of this paper is an exploration of individual differences in 'perseverance' as a personality trait, based on the initial stages of data collection. While dispositional perseverance was one of many factors assessed in

the baseline survey, during the first series of telephone and email interviews for the study it was also identified by the majority of interviewees as a personal quality or characteristic that is central to success in PhD candidature. As a measure of dispositional 'perseverance and passion for long-term goals', the Short Grit Scale (Duckworth and Quinn, 2009), was employed to examine how self-reported perseverance might be related to various demographic or candidature factors, as well as to a number of different measures of metacognition and affect.

The baseline survey data indicated that mean perseverance scores for participants in this study were relatively high compared to the populations of 'high achievers' studied by Duckworth and colleagues (2007, 2009). Consistent with Duckworth, Peterson, Matthews and Kelly's (2007) findings with the original Grit scale, was the positive trend, evident via ANOVA and Scheffe analysis, between perseverance and age. There were no significant differences associated with stage of candidature. Strong and significant positive correlations were found between perseverance and a number of metacognitive measures, most notably with indicators of a student's sense of hope, agency and self-efficacy. To further investigate the responses to the Grit questionnaire, this paper draws on the findings of a small-scale qualitative study undertaken to explore and describe how PhD students discuss the experience of what could be termed a "crisis of perseverance" – a time of intense uncertainty and distress regarding whether or not to persist with the PhD (Budd, Scevak, and Cantwell, 2010). In an approach enabling a more immediate insight into this experience than that offered by retrospective reflections from attrited PhD students, and enhanced ecological validity through the preservation of participant anonymity, a number of public domain online forum discussions for PhD students were analysed to learn more about the factors at play at the time when quitting was considered.

An analytical approach based on grounded theory (Corbin & Strauss, 2008) was used. The findings of the public forum study identified that, at least for these students, uncertainty about their ability or willingness to persevere with the PhD was often associated with a sense of disappointment that the student's expectations of the PhD and of themselves as PhD students were either unmet or mismatched. Many observed in themselves a change from confident and successful graduate, to depressed, lonely, and uncertain PhD student. There was a dissonance between their expected and actual affective experience of themselves as PhD students, an uncertainty about what this meant, and a waning of motivation. Clearly, the students' decisions about perseverance in doctoral study were closely related to their interpretation of the affect associated with the PhD process. Further, these findings suggest that while such affective dissonance may be a common experience among PhD students, it is not well understood. For example, while this type of affective response and personal change may be associated with the transformational nature of higher level intellectual development usually expected in doctoral study, a lack of awareness of this possibility may result in the interpretation of this experience as indicating a lack of personal ability or suitability for the PhD process. The latter certainly appeared to be the assumption on which many students' discussion comments were based.

Analysis of these online discussions highlighted how misinterpreting this affective dissonance can have potentially serious consequences in terms of perseverance with PhD candidature, ranging from unnecessary attrition to suicidal ideation. The results of the two studies will be discussed in terms of the implications for doctoral pedagogy. In particular, we discuss the importance of, and strategies for, helping students to more comprehensively understand and manage the affective experiences associated with doctoral learning, and identify areas requiring further research.

PAPER PRESENTATION

Creating metacognitive environments in primary Religious Education lessons

Shirley Larkin, University of Exeter, United Kingdom

This paper focuses on the RE-flect project. RE-flect was a collaborative mixed methodology research project designed to create metacognitive learning environments in primary year 5 classrooms. Participants were 10 state run primary schools from one UK local education authority area. In total 10 teachers and 250 pupils age 9-10 years took part in the year long project. The aims of the project were to develop activities to enable pupils in RE year 5 primary classrooms to reflect on and consider their own ontological positions in relation to others; create metacognitively-oriented classroom environments and improve attainment in RE; support teachers in developing their own metacognition in order to reflect on their own ontological positions.

The project draws on theories of metacognition and metacognitively oriented learning environments. The paper provides findings from the quantitative pre and post test measures of attainment in RE and from a scale, REMOS designed to measure pupils' perceptions of their learning environment. An illustrative case study of one school in the project suggests the systemic and local obstacles teachers and pupils face in creating metacognitive environments in religious education lessons.

This paper describes a year long collaborative project between a team of university researchers and ten primary school teachers. The project, RE-flect, was designed to create metacognitive environments in year 5 primary religious education lessons. The guidelines for Religious Education in English Schools: Non-statutory Guidance 2010 (DCSF, 2010) are challenging, suggesting that RE should cover a wide range of goals from provoking questions about the meaning and purpose of life and what it means to be human; to encouraging pupils to explore their own beliefs as well as contributing to community cohesion by promoting tolerance. School inspectors and professional inter-faith groups have criticised the provision of RE in primary schools (Ofsted, 2007). In particular it was found that pupils do not gain a secure conceptual framework within which to fit their learning and teachers lack confidence in teaching a subject in which they are not specialists. It has been suggested that pupils cannot engage with others without first understanding their own beliefs and values ((Inter Faith Foundation, 2006). Without developing the skills to reflect on their own thinking pupils often view RE as simply a "matter of opinion" (Freathy & Aylward, 2010) and thus oversimplify the nuances of difference within faiths as well as the complexity of identity and culture more generally. Baumfield has suggested that the study of pedagogy in RE is "underdeveloped" (Baumfield, 2010). This paper argues that there needs to be a shift in emphasis away from research on content (Hayward, 2006; Rymarz, 2007) or the extent to which the representation of religious traditions may be considered truly authentic (Everington, 1996; Greaves, 1998) or representative (Jackson, 2004; Nesbitt, 2004) towards an emphasis on the pupils' "response, thinking and critical self-awareness" (van der Zee, Hermans, & Aarnoutse, 2006). The RE-flect project seeks to address these specific issues through supporting teachers in creating metacognitive environments.

Metacognition

Metacognition can be defined as everything we know and believe about our own and others' cognitive processes and the regulation and control of our own thinking (Flavell, 1979). Flavell suggested metacognition enables us to "make wise and thoughtful life decisions" (ibid pg910). This project views metacognition as enabling self understanding through a reflection on one's own thinking, beliefs, epistemological stance and values. In this way, metacognition prioritises knowledge of self before engagement with the other. Research indicates that it is not enough to train teachers to facilitate metacognition (Zohar, 2006). Teachers need to develop their own metacognition (Duffy, Miller, Parsons, & Meloth, 2009). It is plausible that some of the difficulties encountered by non-specialist teachers of RE are linked to a lack of metacognition.

This project aimed to provide teachers with a framework for developing activities, pedagogy and classroom environments to support the development of metacognition. There is a focus on metacognitive orientation. Metacognitive orientation refers to the extent to which psychosocial conditions that are known to enhance pupils' metacognition are evident within classrooms. The characteristics of metacognitively-oriented learning environments (Thomas, 2003; Thomas & Mee, 2005) suggest that the beliefs and practices of the communities within which students learn to learn and reason strongly influence their metacognition; that specific language plays a key role in relation to communication regarding thinking and learning processes to and between pupils, and that pupils require particular encouragement if they are to reflect on, critique and possibly alter their thinking processes.

Participants

250 pupils aged 9-10 years in 10 different state run primary schools from one UK education authority
10 teachers with a responsibility for teaching religious education in these schools.

Research Aims to:

develop activities to enable pupils in RE year 5 primary classrooms to reflect on and consider their own ontological positions in relation to others; create metacognitively-oriented classroom environments and improve attainment in RE support teachers in developing their own metacognition in order to reflect on their own ontological positions.

Methodology

This is a collaborative project with a mixed methodology design. Pre and post quantitative measures are illuminated by qualitative data collected during the project. Individual case studies of classes within the project provide detail of the classroom practices developed during the project.

Data Collection and Analysis related to the above aims

1. Pupils create "world view profiles" during the project – analysed qualitatively with a focus on ability to express thinking; ability to reflect on ideas and sophistication of ideas expressed
2. Pre, predicted and post level of attainment in RE using standard UK assessment Pre and post scores on REMOS a scale developed to measure pupils' perceptions of the metacognitive orientation of their classroom environment Pre and post semi-structured interviews with 6 focus children in each class 3x10 semi-participant classroom observations,

including video capture of the lesson and activities - data analysed qualitatively using NVIVO and related to a theoretical framework of metacognition

3. 3 methods of developing teacher metacognition – repertory grids, reflective diaries and on-line discussion - data analysed using content analysis, concordance analysis and discourse analysis

EthicsBERA ethical guidelines were adhered to. Special consideration was given to ethical issues surrounding using reflective diaries as data and to supporting participants through the processes of producing repertory grids and reflecting on thinking.

Findings

The paper presents headline findings from the pre and post measures along with an illustrative case study which illuminates the way teachers and pupils worked together to create metacognitive environments in one RE classrooms. Preliminary data is showing that teachers face a number of system level challenges to creating such environments, these are connected to UK policy on religious education in primary schools and to wider educational factors such as whole school attainment targets. The project ends in July 2011 when the quantitative data will be available.

Discussion and ImplicationsThe paper will discuss the findings in relation to theories of metacognition and the creation of metacognitive environments. Implications for teacher development will be drawn and suggestions for future research made. It is not possible to detail these implications until the project ends.

PAPER PRESENTATION

Rethinking the scope of Metacognition: a multi-dimensional account

Robert Cantwell, University of Newcastle, Australia; Jill Scevak, University of Newcastle, Australia; Sid Bourke, University of Newcastle, Australia; Krystyna Cholowski, University of Newcastle, Australia

In this paper, we report on a study of metacognition in PhD students, examining the possibility that identified individual differences may well reflect variations at an epistemic rather than componential level. Following Veenman et al. (2006), we speculate that the scope of metacognitive knowledge includes more than strategic regulation. We suggest metacognitive knowledge also provides a higher order, multi-dimensional dispositional framework that guides the affective, intellectual and contingency appraisals individuals must make in generating regulatory decisions.

263 PhD students completed measures relating to the management of intellectual, affective and contingency demands in candidature. A two-step cluster analysis discriminated two groups differing significantly across all measures. Factor analysis identified three dimensions to the responses: "Coping" with the intellectual, affective and contingency response demands of learning; "Naivety" in conceptualising the intellectual demands coupled with a diminished sense of competence and commitment; and "Disengagement", through diminished understanding of the intellectual demands combined with an abrogation of responsibility for progress. Third, analysis of variance indicated that Cluster 1 members more highly Coping, Cluster 2 members more highly on Naivety and Disengagement.

We interpret these results as evidence of the multi-dimensional nature of metacognitive knowledge. The differences in the strength and direction of affiliation with the three factors (Coping, Naivety and Disengagement) by the two groups suggest differences in the qualities of the active metacognitive knowledge base driving engagement with the doctoral task. Such differences in epistemic metacognitive frameworks have the potential to provide explanations of problematic candidature and inform developments in supervisor pedagogy.

Traditionally, metacognitive research has focused on self-regulatory capacities and their relationships to planning, monitoring and evaluative behaviours. More recently, research has begun to extend the remit of metacognition in learning to minimally acknowledge the relationships between regulatory decision-making and other, perhaps more general, domains of individual differences. Veenman et al., (2006) gave impetus to this process by identifying the need to examine metacognition in the context of other individual differences, although they did not extend this to suggest a more general unified metacognitive construct to account for individual differences in learning. Nonetheless, there has been some movement in extending the scope of explanation of effective metacognitive activity. A recent special issue of the journal "Metacognition & Learning" (April, 2010), for example, considered the relationships between epistemology and metacognition. For many of the contributors, the link between epistemic beliefs and metacognitive behaviours was emphasised, giving rise to at least some degree of a recognition of the potential mutuality between epistemological and metacognitive beliefs (see Mason et al, 2010; Richter & Schmid, 2010; Muis & Franco, 2010; Bromme, Pieschl & Stahl, 2010). It is our position that this observed link represents only one of many potential associations between domains of individual differences and regulatory behaviour (see Veenman et al. 2006) and that the aggregate of these potential associations may provide evidence of a more generalisable model of metacognition that explicitly acknowledges the interdependence of a multitude of potential sources of individual differences in explaining how specific regulatory decisions are derived and acted upon.

In this paper, we report on a study of metacognition in PhD students. We see the PhD as a useful medium through which the nature of metacognition can be explored. The PhD is first and foremost difficult, requiring candidates to manage intellectual tasks ranging from the basic technical through to those requiring mastery of quite high levels of complexity and abstractness. The PhD also requires completion of a multitude of (related) tasks over an extended time period. Thus the regulatory demands of the PhD exist at many levels, and require maintenance over an extended period of time. Moreover, the PhD is not only about regulation of intellectual activity: it also involves the regulation of affective responses which over time will be as many and varied as evident in the intellectual demands. Finally, as a function of both difficulty and extended time, the PhD also involves the ongoing management of the potential challenges and difficulties in candidature: how the student responds to contingency is also an issue of regulation.

In this study, 263 PhD students completed a battery of instruments relating to the management of intellectual demands (Need for Cognition, Metacognitive Awareness, Epistemological Beliefs), affective demands (Efficacy, Coping) and contingency demands (Volition, Responsibility, Procrastination) of candidature. The analysis focused on three questions: a) whether, as an elite cohort, doctoral students could nonetheless be discriminated on the basis of responses to these questionnaires, b) whether there was an underlying dimensionality to the responses to the questionnaires, and c) whether identified groupings within the cohort differed in their level of affiliation with identified dimensions in the responses. In relation to the first question, a two-step cluster analysis identified two clusters differing significantly across all measures. In relation to the second question, factor analysis identified three dimensions to the responses: "Coping" with the intellectual, affective and contingency response demands of learning; "Naivety" in conceptualising the intellectual demands coupled with a diminished sense of competence and commitment; and "Disengagement", through diminished understanding of the intellectual demands combined with an abrogation of responsibility for progress. In relation to the third question, analysis of variance indicated that Cluster 1 members identified more closely with the Coping factor, while Cluster 2 members identified more closely with the Naivety and Disengagement factors.

We interpret these results as providing evidence for the possibility of a multi-dimensional account of metacognitive knowledge. In the first instance, the cluster analysis provided evidence of heterogeneity within the doctoral cohort. Because the differences between the cluster groups were both significant and spread across all measures, and because these differences were consistently in the appropriate direction, we concluded that the students comprising Cluster 1 had a broader and more strongly internalised base upon which to generate appropriate regulatory interventions. That is, this group likely had, at an epistemic level, a more functional metacognitive framework with which to manage the intellectual, affective and contingency demands of candidature, a framework that included not only the basic self-regulatory skills of conventional descriptions of metacognition, but also the broader epistemological, efficacy, coping and volitional dimensions that provide the conditions for effective regulation to occur. The results of the factor analysis and subsequent ANOVAs gave support to this interpretation. The differences in the strength and direction of affiliation with the three factors (Coping, Naivety and Disengagement) by the two cluster groups suggests differences in the qualities of the active metacognitive knowledge base driving engagement with the doctoral task. Such differences in epistemic metacognitive frameworks, we argue, have the potential to provide explanations of problematic candidature and inform potential developments in supervisor pedagogy.

PAPER PRESENTATION

A New Framework for the Conceptualization of Epistemic Cognition

Clark Chinn, Rutgers University, United States; Luke Buckland, Rutgers NJ, United States; Ala Samarapungavan, Purdue University, United States

In previous work (Authors et al., 2010a, 2010b) we have considered how ideas prevalent in the philosophical literatures of analytic epistemology and the philosophy of science might be used to extend and improve educational research on epistemic cognition. Research on epistemic cognition examines cognitions, especially beliefs, about knowledge and the conditions and processes of attaining knowledge (e.g. Hofer and Pintrich, 1997). Our expanded framework for models of epistemic cognition includes five categories: (1) epistemic aims and their interactions with non-epistemic aims, (2) the structure of knowledge, (3) the certainty, sources, and justification of knowledge, (4) epistemic virtues and obligations, and (5) the reliable processes by which knowledge is achieved. These categories capture many epistemic topics and concepts that feature in the philosophical literatures, but which have not yet featured in extant educational research. In this paper we further elaborate the framework, and provide a more detailed analysis of how philosophers have elaborated on the topics within these five categories. We also develop systematic analyses of the ways in which educational researchers' conceptualizations of epistemic topics diverge from those of philosophers. We argue that an expansion of the dimensions of models of epistemic cognition provides psychologists and educators with rich theoretical resources that can better explain students' thinking and learning.

A New Framework for the Conceptualization of Epistemic Cognition

Goals

Epistemic cognition refers to cognitions about topics such as knowledge and how people come to attain knowledge. The most prominent framework for conceptualizing epistemic beliefs in current educational research derives from the landmark work of Hofer and Pintrich (1997) which characterizes these cognitions in terms of four dimensions: (1) the degree to which knowledge is viewed as simple versus complex, (2) the degree of certainty of knowledge, (3) the sources of knowing, and (4) the justification of knowing. In this paper we aim to expand on this seminal framework by drawing on philosophical work to identify additional topics that educational researchers could investigate.

Method

We have extensively reviewed two philosophical literatures that discuss epistemological topics: analytic epistemology and the philosophy of science. We analyzed epistemological topics and subtopics covered in 150 significant contemporary philosophical books as well as numerous articles from prominent philosophical journals. From these sources, we developed a list of significant topics related to epistemic cognition. As a result of our analyses, we argue that epistemic cognition should be viewed in a more expansive manner than educational researchers have done. We argue specifically that important topics for researchers of epistemic cognition fall into at least five distinct categories, which we briefly describe below.

A Philosophically-Grounded Framework for Conceptualizing Epistemic Cognition

In previous work (Authors et al., 2010a, 2010b), we have provided a broad overview of the five categories of epistemic topics. In the paper for EARLI, we will provide a much more detailed analysis of how philosophers have elaborated on the topics within these five categories, and we will provide a new, systematic analysis of the differences in the frameworks of educational researchers, on the one hand, and philosophers, on the other. Given the space limitations of this proposal, we can here provide only a brief introduction to topics in these five categories. In our paper and presentation, we will provide elaborated analyses of important topics within each of these categories as well as a detailed analysis of the ways in which educators' conceptualizations of epistemic topics diverge from those of philosophers. We will argue that philosophical work suggests many new issues that could be productively addressed in future educational research. The five categories are as follows:

1. Epistemic aims and their interactions with non-epistemic aims. Philosophers have extensively investigated different kinds of epistemic aims (e.g., acquiring true beliefs, avoiding false beliefs, developing powerful explanations, and so on). They have asked what kinds of knowledge people value and thus what epistemic aims they adopt (e.g., do people seek knowledge for its own sake, or knowledge because it is useful in helping them achieving other aims such as wealth or happiness). We will summarize a broad range of issues relating to epistemic aims that philosophers have viewed as important to understanding epistemic cognition. We argue that educators have seldom addressed what epistemic aims students adopt or what their beliefs are about what kinds of aims should be adopted.

2. Structure of knowledge. Current psychological and educational research on epistemic cognition has addressed the complexity versus simplicity of knowledge. Philosophical work suggests the need to investigate more than just this one aspect of the structure of knowledge. As one of many examples we will provide, EC researchers could also examine the degree to which knowledge is viewed as universal (i.e., knowledge applies very broadly) versus contextually (i.e., knowledge is very specific to particular situations).

3. The certainty, sources, and justification of knowledge. Our third category encompasses the certainty, sources, and justification of knowledge. (We include certainty within this category because philosophers treat certainty as a function of the strength of the justification of knowledge, so that degree of certainty is closely tied to strength of justifications.) These are categories that have been explored by many educators. However, philosophers identify many specific issues within these broad categories that have been unexplored by psychologists and educators.

4. The ethics of knowledge: epistemic virtues and obligations. Epistemologists extensively investigate epistemic virtues such as intellectual honesty, intellectual courage and open-mindedness. They also address issues of epistemic obligations—an example of this is the extent to which one is obligated to seek out information on different kinds of questions, such as the extent to which one is obligated to have a certain level of economic knowledge when voting on economic issues. EC researchers have addressed a few epistemic virtues, especially open-mindedness. Philosophical research suggests many other virtues that could be investigated, and we will present a taxonomy of these virtues. Philosophical research also suggests new avenues of research on epistemic obligations, which have not yet been investigated by psychologists or educators.

5. Reliable and unreliable processes for achieving knowledge. Epistemologists and philosophers of science intensively study processes by which knowledge is reliably produced. For philosophers who focus on these reliable processes, a belief is justified (roughly speaking) if it results from a reliable belief-forming process (or set of processes). Philosophers who address these processes ask questions about the conditions under which different

processes do and do not promote knowledge. For example, philosophers may ask questions such as these about social processes of knowledge production in the mass media: What media processes promote societal knowledge, and which do not? Under what conditions do particular media processes (such as televised debates between experts) promote knowledge? Under what conditions do such debates promote knowledge in society, and under what conditions do they not? We think that there is little research by EC researchers on students' beliefs about reliable and unreliable processes for achieving any epistemic aims, including true beliefs. We will present an analysis of the many types of reliable processes that philosophers have examined as important to epistemic cognition.

In this proposal, we have provided a brief overview of our philosophically-grounded framework for epistemic cognition. In the full paper, we elaborate on the specific issues that philosophers have addressed, and we show by expanding the issues included under epistemic cognition, psychologists and educators will gain theoretical resources that can better explain students thinking and learning. We will show how this framework can be applied in educational research.

PAPER PRESENTATION

Young Children's Experiences through Transition between Preschool and Primary School in Chile

Daniela Jadue Roa, University of Cambridge, United Kingdom; David Whitebread, University of Cambridge, United Kingdom

Full Title: Young Children's Experiences through Transition between Preschool and Primary School in Chile and its Relation with their Developing Resilience and Sense of Agency. Abstract: This paper discuss the preliminary findings of an ongoing PhD research in its last phase. This research was carried out in a State school in Santiago de Chile, with 16 young children aged 5 to 6 years during their transition between preschool and primary school. The research design is a multiple-case study within a bio-ecological perspective (Bronfenbrenner, 2005) and therefore, data was gathered from children, their parents and their practitioners. Video-recording, photograph interviews (book-making and poster-making), were carried out with children; the 'Children's Independent Learning Development (CHILD 3-5)' Checklist (Whitebread, Coltman, Anderson, Mehta, & Pino-Pasternak, 2005) was applied by practitioners and semi-structured interviews supported by a questionnaire (Dockett & Perry, 2000a, 2000b, 2000c, 2000d) were carried out with practitioners and parents or caregivers. The purpose of this study is to explore the transition process that Chilean young children experience between preschool and primary school and its relation with their developing resilience (Cefai, 2008; Dunlop, 2003c) and sense of agency along this period (Bandura, 1982, 1993; Bruner, 1996). This study was organized in two phases (before and after transition) and it was developed between September 2009 and August 2010.

The present study was inspired by the proposal of 'The Mosaic Approach' (Clark, 2005; Clark & Moss, 2001); by the research carried out in Australia by Dockett's and Perry's (2007) the 'Starting School Research Project'; and by Dunlop's (2003a, 2003b, 2003c) research study carried out in Scotland. Accordingly, the present study aims to explore young children's experiences in the context of an early transition between preschool and primary school in Chile, and how these experiences relate to their developing resilience and sense of agency within an educational context. Hence, this research intends to answer the following research questions:

Main question: How do young children's experiences of transition between preschool & primary school in Chile relate to their developing resilience and sense of agency?

- Further questions:
- a) How do young children experience transition between preschool & primary school in Chile?
 - b) How do parents experience young children's transition between preschool & primary school in Chile?
 - c) How do practitioners experience transition between preschool & primary school in Chile?
 - d) How do young children's resilience and sense of agency develop during their transition between preschool & primary school in Chile?

To answer these questions, the research was designed with a multiple case study approach within a bio-ecological perspective (Bronfenbrenner, 2005). Taking this into account the research methods are child-centred and seek to

gather young children's perspectives on their own experiences. Therefore, visual and participatory methods such as photography, video recording, book-making and poster-making were used (Clark, 2005; Clark & Moss, 2001, 2005; Jones, 2004; Veale, 2005). In addition, and with the aim of acknowledging the social constructivist perspective of the research design proposed, data was also gathered from adults involved with the young children participating on this study. Practitioners used the 'Children's Independent Learning Development (CHILD 3-5)' Checklist (Whitebread, et al., 2005) to assess young children's self-regulatory skills; and practitioners and parents or caregivers participated in semi-structured interviews guided by the Questionnaire developed by Dockett & Perry in their 'Starting School Research Project' (Dockett & Perry, 2000a, 2000b, 2000c, 2000d). In other words, this design aims to acknowledge young children's voices and agency through their learning and developmental processes. Young children's voices are reflected in this research project by the recognition of their agency and by the inclusion of them as valid informants and active participants in research concerning their experiences (Cousins, 1999; UNICEF, 1989). Taking into account that the school year in Chile goes from March to December and the characteristics of the study, the data collection process was organised in 2 phases: (1) Phase One, from September 2009 till December 2009; and (2) Phase two, from March 2010 till August 2010.

Phase one considered a familiarisation time, video-recording of classroom activities (with a special focus in the classroom interactions); the application of the 'Children's Independent Learning Development (CHILD 3-5)' checklist (Whitebread, et al., 2005); photographs interviews with the book-making activity; and semi-structured interviews with adults participants. The purpose of selecting the book-making session as the first photograph interview was to help young children to engage with the researcher and to help them being confident to share their experiences and reflections on kindergarten. During Phase two the same data collection process was repeated, however, photograph interviews involved the poster-making activity. The purpose of doing a poster in this second phase is to help young children with reflecting about things that have changed in first grade. They are invited to think about what young children need to know about primary school, and to discuss why; also what can schools, teachers and families do to help children who are starting primary school (Margetts, 2006). All these questions are also explored with adults involved in the semi-structured interviews carried out with them.

The data analysis has had as a main purpose the co-construction of meaning with young children's perspectives and adults involved in their experiences. Therefore, data has been coded grounded in what the data reveals and supported with the theoretical framework presented for the present study. Two main coding schemes have been developed: one regarding young children's perspectives on transition; and a second one related with their expressions of resilience and developing sense of agency. In order to ensure that during this process the focus is young children's voices and the construction of meaning, the following principles for listening to young children developed by Clark and Moss (2001, 2005) have been acknowledged: . 'it is an active process of communication involving hearing, interpreting and constructing meanings . Not limited to the spoken word . A necessary stage in participation in daily routines . Participation in wider decision-making processes' (Clark & Moss 2005, p. 8) In sum, this paper invites to a discussion about preliminary findings of young children experiences in their transition and their demonstrated resilience and sense of agency. Present findings can be discussed in the light of the outcomes of previous research carried out in the field and its contributions to further research in this context are considered. Lastly, this paper aims to reflect upon the contributions of visual methods in participatory research with young children, their effectiveness in helping the researcher to listen to young children's perspectives and, particularly, young children's perspectives in the context of an early transition in Chile.

Young Children's Perceptions of the Nature and Functioning of Artifacts with Adaptive Behaviour

David Mioduser, Tel Aviv University, Israel; Asi Kuperman, Tel-Aviv University, Israel

This study examines the effect of experimenting with advanced-robotic technological systems on young children's perceptions of the Nature and functioning of controlled artifacts with adaptive behavior. 10 kindergarten children performed a series of explanatory and programming tasks of increasing complexity, in terms of the expected robot's adaptive behavior. The research questions focused on: (a) children's perceptions of behaving artifacts, whether these reflect a psychological/behavioral or a technological/functional perspective, and (b) children's ability to program behaving artifacts focusing on the representational structures used for expressing the robot's behavior (e.g., scripts or rules) and on the troubleshooting processes (debugging). Findings are indicative of young children's (both "explainers" and "programmers") ability to conceptualize the robot's behavior using a technological perspective. As well, the results convincingly show "programmers" ability to construct complex robot behaviors. Moreover, we observed children's ability to use generalizable, a-temporal and abstract representations of the desired behaviors (e.g., rules), seemingly a serious challenge for kindergarten children according to existing literature. It seems that the interaction

between the concrete (the physical robot and its actual functioning) and the abstract (the symbolic interface for constructing and debugging the control program) supported children's performance at sophisticated cognitive levels.

Kindergarten Children's Perceptions of the Nature and Functioning of Artifacts with Adaptive Behavior David Mioduser, Asi Kuperman Tel-Aviv University Children are exposed nowadays from a very young age to controlled technological systems. A visit to the nearest supermarket introduces them to automatic doors, barcode readers or controlled conveyor belts. Many toys they play with are programmable? and at home they interact with complex devices such as controlled appliances, mobile phones and computers. In recent years, children from a kindergarten in central Israel have been exposed to experiences with simple robots as part of the implementation of a curriculum focused on technological thinking. The curriculum has been developed upon the idea that technological thinking integrated into the kindergarten's culture will stimulate the children's curiosity and will support, and even demand, the use of high-order thinking, analytic capabilities, abstraction and problem solving, laying out the road to meaningful knowledge building processes. Such technological-thinking related skills are not part usually of the curriculum in kindergartens.

This study examines the influence of experimenting with advanced-robotic technological systems on children's perceptions of the Nature and functioning of controlled artifacts with adaptive behavior. The main goal was to explore how kindergarten children perceive and program the behavior of an adaptive robot.

Method

The population included 10 kindergarten children aged 5-6 (chosen randomly from a group of 25). Data was collected using observations and interviews. A qualitative research paradigm was chosen for the study, due to the small sample. Two types of tasks were implemented: (a) explanatory tasks in which children were requested to describe and explain the observed behavior of a robot, and (b) programming tasks of a robot's adaptive behavior. The tasks were built as a progression of increasing complexity, defined by the number of program components (e.g., rules, routines) required for generating the robot's behavior. The programming environment, "RoboGan", was developed for kindergarten children. It is icon-based, enabling to define the control rules in intuitive manner not requiring reading or writing code. The research questions addressed in this presentation focus on: (a) children's perceptions of behaving artifacts: whether these reflect a psychological/behavioral or a technological/functional perspective. (b) children's ability to program behaving artifacts, focusing on the representational structures used for expressing the robot's behavior (e.g., scripts or rules) and on the troubleshooting processes (debugging).

Findings

On children's perception of the robot's behavior Findings indicate that the children referred unevenly to the robot as a behaving artifact from psychological/behavioral and technological/functional perspectives. The utilization of anthropomorphisms (as indicator of a psychological perspective) was not dominant, compared to usage of technological language (Figure 1). When used, it was mostly due to the linkage made by the children to the task's underlying story, thereby recurring to the usage of anthropomorphisms, e.g.: "walking on the bridge", "careful not to bump into an obstacle", "getting the goal". In contrast, the technological perspective, and the usage of technological language, was dominant. This finding emphasizes the children's ability (both "explainers" and "programmers") to conceptualize the robot as functioning artifact. Figure 1: Children's perception of the robot's behavior as a function of task complexity A decrease in the use of anthropomorphisms as the task's complexity increases was observed both amongst the 'explainers' and the 'programmers'. This indicates that in more complex tasks children describe what they see or do in more "professional" terms. Thus for complex behaviors, anthropomorphism is not sufficient - when children understand the connection between the task, the robot and the interface, they perceive the robot from a technological/functional perspective. This indicates also children's ability to establish the linkage between the robot as concrete artifact and the programming environment as abstract or symbolic space. This abstraction is evident in the children's explanations, in their analysis of the robot's behavior and in the capabilities they exhibit in the programming process.

On children's ability to program the robot's adaptive behavior Among alternative constructs used for representing a device's behavior, in this study we focused on three: episode (description of a one-time event), script (a sequence of events in a temporary structure and re-usable as routine) and rule (general and a-temporal construct, using condition/action terms such as "if... then..."). Findings indicate that children were able to use all three constructs, as required by the programming tasks (Figure 2). Usage of rules indicates the ability of kindergarten children to generalize and use a-temporal abstract representations, something seemingly beyond the capabilities of kindergarten children according to existing literature. Additional support to this claim in the findings is the relatively low usage of episodic descriptions. The programmers seldom used concrete terms for describing the robot's behavior, and were

inclined to use the more complex structures (i.e scripts and rules). Figure 2: The robot's behavior representation as a function of task complexity

Regarding troubleshooting and problem solving, different strategies were used by the children until satisfactory completion of the task was reached, e.g. deleting the whole program and starting over, or replacing one command at a time till the expected behavior was observed. In summary, technological thinking entails an important, interesting and unique experience which has the potential to contribute to young children's conceptual understanding, problem solving and learning of complex phenomena in the everyday environment. Kindergarten children are at a stage in which their curiosity is at its peak. They ask, examine and try to discover the world in which they live in, hence meaningful authentic and relevant experience leads to learning. The tasks they were exposed to were real: they were required to learn and to use their acquired knowledge to fulfill tasks in the real world: programming a functioning artifact in the real world. These conclusions encourage the need for further studies focusing on implementation of technological thinking in the kindergarten curriculum as well as on additional questions beyond the scope of this study, e.g. the importance of adult mediation, mental models developing from these experiences, educational tools which may be developed following the study's findings, and naturally, the collaborative learning taking place in technological thinking-based group activity.

PAPER PRESENTATIONS

Teacher's talk about toddler's early literacy experiences at preschool

Sara Hvit, Jonkoping University, Sweden; Polly Bjork-Willen, Linkoping University, Sweden

Early literacy experiences are important parts of toddler's literacy development at preschool. The importance of children's literacy is also emphasized in the new Swedish preschool curriculum. Kress (1997) points out, that a literary sign is a combination of meaning and form, and that the meaning making should be seen in a social and cultural context as well as an activity. From this point of view young children's literacy does not consist of reading and writing only. It also includes all visual information that communicates to the children in their everyday world. The present paper aims to explore how teacher teams at 10 diverse preschools during focus group interviews, talk about and discuss toddler's literacy experiences. Detailed analyses of the interviews are made. The analyses show that three main areas of toddlers' literacy are highlighted in the talk; 1) toddlers' own manifestation of literacy, 2) how to work with toddlers' literacy, and 3) what characterizes the literacy environment. However, the majority of the teams were not used to verbalize and openly discuss toddlers' literacy and its implication on the preschool practice. The latter finding is a challenge for the teacher education and the implementation of the new curriculum.

Aim and theoretical background. In Sweden most children begin preschool at the age of one, and 80 % of the children between one to three years old go to preschool for education and care on a daily basis (Skolverket, 2009). Hence, the way the curriculum is implemented is of great importance for the children's learning and development, particularly when the youngest children aged one to three (named toddlers in the present paper) are concerned. In the new curriculum for the Swedish preschool there are clarifications in the area of language and communication. Language and communication are described as inextricably connected with children's identity and understanding of self and others (Ministry of Education, 2010). Furthermore the curriculum calls attention to the fact that language environment in preschools should offer children opportunities to explore and use written language. The conclusion drawn from the curriculum outline above is that the expectations laid on the preschool teachers' way of realizing a 'good' language environment are very high.

The focus of this paper is to investigate the language environment for toddlers at preschool, and the study takes its theoretical starting point from Barton's (2007) ecological view of literacy. It also uses a multimodal approach of children's meaning making in different modes (Kress, 1997, 2010). Consequently, to understand toddlers' intentions in literacy events, it is important to pay attention to their verbal as well as non verbal way of expressing themselves and to create meaning (Lökken, 2006, 2009). More specifically the aim is to explore how literacy is talked about and discussed by teacher teams working with toddlers.

Method

In the present study focus group interviews with ten teacher teams are analyzed in detail with respect to the teachers talk about literacy events with toddlers. Each team was interviewed at two distant occasions, hence the data includes in total 20 interviews. The interviews originate from a larger corpus of interview data and this in turn is a part of a comprehensive study that investigates preschool as a context for children's language development at 60 preschools, being equally distributed over three communities in Sweden. As the literacy of toddlers is the focus of the present study, only interviews with teams working solely with toddlers were selected. The interviews were transcribed, and a collection of sequences including the teachers' talk and discussions about literacy and literacy events were selected

for the analysis. Transcriptions were prepared using conversation analytic notations (cf Hutchby & Wooffitt, 1998). The sequences of talk were analyzed in detail with a participant-oriented perspective on interactional conduct (Schegloff, 1999). All names of persons and places have been changed to preserve participants' anonymity.

Preliminary findings

Preliminary findings indicate that literacy is defined and discussed in most varying ways between the teams, but also within a team. To verbally express what signifies toddlers' literacy seemed to be an unusual issue for many of the teams. Although, the areas that gradually became emphasized were 1) toddlers' own manifestation of literacy, 2) how to work with toddlers' literacy and 3) what characterizes the literacy environments. When literacy was described from the perspective of the child, a common description in the interviews were how toddlers use books, and how obvious it is that toddlers identify themselves as readers as well as writers. For example it was described how the children read for each other and for the dolls, and that they turn the pages and sounds like reading. The toddlers also encourage their listeners to be really quiet and listen carefully (c.f. Björk-Willén & Cromdal, 2009). However, most of the teams declare that they oppose to teach toddlers reading and writing. They preferred methods that are embedded in everyday practice, and that literacy should be highlighted in situ, for instance asking a child "do you want to read for me or do you want me to read?", or "what are you writing? ". One of the teachers points out that "the physical language environment in total aims to learn them (the children) to read and write, but we do not coach them to read and write". The environment and the pedagogic material are not referred to as an isolated unit, but the connection between physical aspects of the environment, language and teaching attitudes are often discussed in the interviews. So is the kind of artifacts and its locations that are used to improve toddlers' literacy.

Theoretical and educational significance of the research

The teachers' talk and discussions about toddlers' literacy strengthens the way of viewing toddlers style (i.e. Lökken, 2006, 2009) and their manifesto of literacy (Björklund, 2008). The discussions about the language environment also have a clear multimodal approach to small children's literacy (see Kress, 2010). However, the teacher's talk about toddlers' literacy was unreflecting and based more on experiences than theory. The talk also derives from a play based rather than a teaching view of toddlers' early literacy.

PAPER PRESENTATION

Early development of self-regulation and the use of communicative signs in educative interactions

Marisol Basilio, Universidad Autonoma de Madrid, Spain; Cintia Rodriguez, Universidad Autonoma de Madrid, Spain

From a socio-cultural approach, the role of language as a tool to support the self-regulation (SR) of physical and cognitive activity has been widely studied, yet there is little evidence on the role of pre-linguistic semiotic systems in the early development of self-regulatory skills. By extending Vygotsky's hypothesis on the development of SR to a pre-linguistic level, the purpose of the study is to analyze the transition from other-regulation to SR through mediated activity. We observed four children longitudinally at 11, 13 and 15 months old in triadic interaction (child-adult-object) with one of their parents. The object for the interaction was a toy which conventional use requires the understanding of rules, the execution of successive sequences of actions and the use of a hammer as an instrument. We coded for parents' use semiotic utterances to scaffold the object's conventional uses to their children, (i.e verbal utterances, demonstrations, ostensive signs, pointing gestures, etc), and for children's use of signs related to their activity

(ostensive gestures, pointing gestures, vocalizations). Parents used complex semiotic mediators during the interaction, and children engaged in progressively more complex conventional uses of the object over time. We identified 44 events in which children used pre-linguistic signs with a self-regulatory function (4, 4 and 36 at 11, 13 and 15 months old respectively). We analyzed and classified these events according to their semiotic modality and their function. We present qualitative observations that illustrate these categories.

A global networked society means fast changes that demand for the ability to adapt to new circumstances. Supporting children to become self-regulated independent learners is probably one of the most important goals of education in this context. During the last decades, the awareness of the importance of quality Early Years Education especially during the 0-3 period has increased. From a vygotskian perspective, the role of language as a tool to support self-regulation (SR) has been widely studied (on children older than 3 years old, Winsler, 2009)) and numerous educative tools have proven to effectively promote SR. However, there is little evidence on the role that pre-linguistic semiotic systems might play in the early development of self-regulatory skills (i.e. Rodríguez & Palacios, 2007, Valloton, 2008, Delgado, Gómez y Sarriá, 2009).

This study aims to address this gap in the literature. We aim to understand when and how do children start using semiotic tools with a self-regulatory purpose. Understanding the early development of SR and its relation with non-linguistic semiotic tools, has great implications for early years education. The questions of the study are: (1) what kind of communicative semiotic tools do parents use to regulate the children's behavior? (2) Do children use similar communicative semiotic tools (ostensive gestures, pointing gestures, vocalizations) to regulate their action, either directed towards the adult, or to themselves?

Four infants and one of their parents were videotaped at their homes while interacting with a complex object during five minutes. The object of the interaction is described in Basilio & Rodríguez (in press) It is a wooden toy with different parts: a box with three holes on the top, three balls that fit in the holes, but they do not fall inside the box unless they are pushed down. There is a hammer to hit the balls and push them down and make them fall. The bottom of the box is inclined so the balls exit through a hole in one side of the box (Figure 1). Parents were told to "Play with their babies as they would normally do".

We conducted a microgenetic analysis of interactions from a semiotic-pragmatic perspective of development and objects (Rodríguez and Moro, 1999). We coded for parents use semiotic utterances to scaffold the object's conventional uses to their children, (verbal utterances, demonstrations, ostensive signs, pointing gestures, symbolic gestures), and for children's use of signs related to their activity (ostensive gestures, pointing gestures, vocalizations). We identified 44 events in which children used pre-linguistic signs with a self-regulatory function (4, 4 and 36 at 11, 13 and 15 months old respectively). We analyzed and classified these events according to their semiotic modality and their function. We present qualitative observations that illustrate these categories. We describe the categories used to characterize these behaviours (both, used in previous studies and developed in this study) and we analyze observations that illustrate them. The following is an example.

Observation 4. duration: 28 seconds.

C1 (Child 1, girl) 15 months old; A (Adult, father)

Indexical sign, Ostensive gesture and vocalization; requesting specific help to the adult.

C1 hammers the balls that she has placed in the holes previously. A encourages her action saying "Very good, very good, very good, another one, come on!". C1 hammers over the box, but does not aim at any specific ball, so she just manages to introduce partially the three of them, but none of them would fall inside the box. C1 stops hammering and tries to take out one of the balls. A grabs the child's hand holding the hammer and says "it's about to fall, it's about to fall. Once again, once again, hit it one more time", directing her arm so that the hammer is over a ball, and making the movement up and down, like hammering but not hitting the ball. Then A, holds N1's arm higher and says "come on, you hit it!" letting her arm go, so when it falls it hits the ball with the hammer and makes the ball fall into the box. A celebrates saying "Good!". After this immediate demonstration. N1 takes the ball from the exit hole, she places it again and hammers three times, but doesn't manage to hit the ball. A says "Come on, hit it harder". Then C1, points at the ball with the hammer, she looks at her father's hand and still holding the hammer, she shows him her wrist and vocalizes "hmm", requesting for his help to hammer. A grabs her hand and says "Do you want me to help you? Come on" and guides her hand hammering with her until the ball falls into the box.

In this observation the child has the goal of hammering the ball, but she is not succeeding. After trying by herself, she asks the father to help her. She manages to communicate him what she wants without words, using an indexical sign (when she points toward the ball using the hammer) an ostensive sign (when she shows her wrist with her hand holding the hammer) and a vocalization. The father understands her intention and helps her, so she succeeded in her

goal. This behaviour indicates that the girl, as young as 15 months old is capable of: - holding a goal in mind, - she understands the sequences of actions necessary to complete the goal, - she knows that her father can help her, - and she communicates effectively what she wants. In this case, she is not yet capable of achieving the complete use of the object but herself, but instead of giving up and do something else, or instead of giving the hammer to the father for him to do it, she keeps the hammer, and request for help in the specific part of the action where she has difficulties. We conclude that sensitive microgenetic analysis of triadic interactions allows to evidence that children develop self-regulatory skills even before they learn to use language, non-verbal communicative tools also fulfil a self-regulatory function from early in life.

PAPER PRESENTATION

Antecedents and consequences of initial and sustained interest during a learning task

Anna Tapola, University of Helsinki, Finland; Marjaana Veermans, University of Turku, Finland; Markku Niemivirta, University of Helsinki, Finland

In two related studies, the change in students' on-task interest was examined as a function of individual and task characteristics. Elementary school students worked in two groups with a different simulation task type to learn the basics of electricity. Students' personal goal orientations and interest in math and science were measured before the task. Pre- and post-tests were used for measuring relevant content knowledge on the subject. On-task interest was recorded repeatedly in different phases of the task. The results of Study 1 (n=52) were tested for replication and extended with measures on students' self-reported use of motivational regulation strategies in Study 2 (n=120). Repeated measures ANOVA and partial least squares method were used for analysing the data. The role of task characteristics in students' on-task interest was reflected in the results showing, first, that the general level changes in on-task interest were different in the two simulation task groups. Second, the learning outcomes seemed partly to depend on the changes in students' on-task interest, in favour of the task group where an increase in on-task interest was observed. On the other hand, students' initial interest at the beginning of the task depended on their individual characteristics. Time sequenced on-task interest ratings also strongly predicted one another, regardless of the task condition. Students' self-reported tendency to use motivational regulation strategies was related to their on-task interest throughout the task. Discussion focuses on the importance of acknowledging both individual and situational factors in the development of students' on-task interest.

Summary

Introduction

In order to cope with a learning task, students need a sufficient level of initial motivation to get started, as well as maintained motivation to perform it (Sansone & Thoman, 2005). To better understand the formation of this 'motivational chain', integrated knowledge on the factors affecting students' motivational state at the very beginning and during the learning task is needed. The separate roles of various antecedents and consequences of motivational states have been studied within different research traditions. However, there have been only a few attempts to integrate distinct motivational constructs from different theoretical frameworks (Harackiewicz et al., 2008). Also studies that would have examined the dynamic changes of motivation over the course of a learning task are scarce. Objectives Consequently, two related studies were conducted to address these shortcomings. Central concepts of goal orientation and interest theory were used to study the dynamics, as well as the antecedents and consequences of students' on-task interest during a learning task. More specifically, we wanted to know 1) how students' on-task interest change in the course of a learning task, 2) how students' individual and task characteristics affect students' on-task interest, and 3) which factors predict students' learning outcome measure.

Method

In order to examine of the role of task characteristics, a condition comparison was created. Elementary school students (10 to 12 years old) worked either with a semi-concrete or concreteness fading simulation task to learn the basics of electricity. Before the simulation task, students' personal goal orientations and subject-specific interest in math and science were measured. Taking into account the dynamic nature of on-task interest (Ainley & Hidi, 2002), repeated measures in different phases of the task were used. Students' prior knowledge on the subject (pre-test) was measured before, and learning outcomes (post-test) one day after the simulation task. The change in students' on-task interest was analysed using repeated measures of ANOVA. Partial least squares (PLS) path modeling was used to examine the effects of antecedents and consequences of on-task interest.

Results

In Study 1 (n=52), the simulation task condition had an effect on the way students' on-task interest changed during the learning task. Students' level of interest increased among those who were working with the semi-concrete

simulation type, while a decrease in interest was found in concreteness fading condition. However, students' initial on-task interest was dependent on their interest in science and math, which, on their part, mediated the effects of mastery-intrinsic and avoidance orientation on initial on-task interest. It was also found that independently of the task condition, the effects of time sequenced interest measures on one another were notably strong. Further, our results gave indications that the changes in students' motivational state were reflected in their learning outcome measure after the task. At the group level, students who experienced an increase in their interest during the task also performed better in the post-test. In Study 2 (n=120) the same design was replicated with slightly revised methodology and a larger sample. We also wanted to gain more knowledge of the factors related to the development of students' interest during the task. It has been suggested that students' tendency to use motivational regulation strategies affect whether the initial level of motivation will be sustained (Wolters, 2003). We used a modified questionnaire developed by Wolters (1999) to measure students' self-reported use of motivational regulation strategies after the learning task. Thus, we were able to examine students' on-task interest also from the perspective of their self-regulatory tendencies.

The preliminary results of the Study 2 indicated that, as in Study 1, there was an increase in students' level of on-task interest in the semi-concrete simulation condition. In the concreteness fading condition, on-task interest maintained at the same level throughout the task. The effect of mastery-intrinsic orientation, mediated by students' interest in math and science, on initial on-task interest was replicated. Like in Study 1, repeated on-task interest measures strongly predicted one another. Students' tendency to use motivational regulation strategies was related to their personal goal orientations (except avoidance orientation) as well as on-task interest measures.[1]

Conclusions

Although acknowledged in theory, there is a lack of empirical studies concerning the changes in motivational states during a learning task. The results of the two studies reported here illustrated the dynamic nature of students' on-task interest. The differences found in the two task conditions showed, first, that besides maintaining students' interest, task characteristics may have the potential to even enhance it. Second, although the level of students' interest was rather high in both conditions throughout the task, it was the positive change that seemed to matter when considering students' learning outcomes. While the general level changes could partly be attributable to the differences in task conditions, the results showed that students entered the task situation with different motivational backgrounds which affected the level of their initial on-task interest. The importance of the initial interest at the beginning of the task was highlighted in its predictive effect on subsequent interests during the task. Further, as shown in Study 2, students who reported having used motivational regulation strategies more often during the learning episode were also more interested throughout the task. The results of the studies speak in favour of acknowledging individual factors that affect, not only the initial level but also the maintenance of students' transient motivational states. Consequently, besides considering the "interestingness of the environment", the influence of students' motivational background should be taken into account in study designs as well as in practical implications.

PAPER PRESENTATION

Motivational approaches to the study of theology in relation to theology students study path

Laura Hirsto, University of Helsinki, Finland

The aim in this study is to explore the relationships between motivational approaches to the study of theology and theology students' curricular choices during their study path. Relationships were explored through follow-up data. During their first year, they completed a questionnaire which included motives for studying theology. On the third and fifth year they were asked to respond to questions concerning their curriculum choices. There are empirical

indications that spirituality is one of the determinants of career behavior (Lips-Wiersma, 2002): it influences career purpose, sense-making and coherence. Duffy and Blustein (2005) argue that individuals who have a strong spiritual relationship with a higher power and are religious through intrinsic motivation tend to be more confident in their ability to make career decisions and are more open to exploring a variety of career options. The theological studies provided an interesting context to investigate religious and spiritual aspects of motivation, for those aspects usually are more detectable in choices of theology students compared to university students in other fields. According to preliminary results, certainty of curriculum choice, curriculum choices and reasons given to them were significantly related to the motivational approaches for the study of theology reported in the beginning of university studies. However, the pattern was different when third and fifth year relationships were compared.

Aims The aim in this study is to explore the relationships between motivational approaches to the study of theology and theology students' curricular choices during their study path. Vocational psychologists have conducted a great deal of research into the effect of contextual variables on career development, but have yet to explore adequately the role of spirituality and religiousness (Duffy & Blustein, 2005, p. 431-432). Theoretically, religious questions are intertwined in the personal worldviews (cf. Hirsto, 2001) and values of students and affect motivational constructs. Spirituality and religiousness can provide people with an ultimate sense of purpose (Emmons, 1999; McIntosh, 1995). There are also empirical indications that spirituality is one of the determinants of career behavior (Lips-Wiersma, 2002): it influences career purpose, sense-making and coherence. Duffy and Blustein (2005) argue that individuals who have a strong spiritual relationship with a higher power and are religious through intrinsic motivation tend to be more confident in their ability to make career decisions and are more open to exploring a variety of career options.

The theological studies provide an interesting context to investigate religious and spiritual aspects of motivation for those aspects usually are more detectable in choices of theology students compared to university students in other fields. Faculties of theology in Finland offer a general theological education and the education required to become a teacher of religion, as well as qualifications for students wishing to become pastors in the Evangelical-Lutheran church. It could be assumed that more students in these faculties than in higher education in general have some sort of spiritual motivations for their study. However, the teaching at these faculties is non-confessional and students come from various Christian spiritual traditions. Studies on motives for studying theology have produced some classifications: a spiritual calling, the instrumental approach, the scientific approach, self-fulfilment, a helping orientation, being assured of a place to study, and other people's influence (Niemelä, 1999; Baylis, Cargas, Hartley, Rowland, Sabri, Stavrakopoulou and Wyatt, 2004). The relationships with motivational approaches and curricular choices will be explored through the following questions: How are the motives in the beginning of the theological studies related to a) certainty of curriculum choice b) curriculum choices, and c) reasons given for the choices in the third and the fifth year of university studies?

Methodology

This is a follow-up study among theology students. During their first year, they completed a questionnaire which included motives for studying theology. On the third and fifth year they were asked to respond to questions concerning their curriculum choices. The response rates were 70.4 % in the first year, 41.8 % in the third year and 25.9 % in the fifth year. Missing data-analysis will be reported in this presentation.

Findings

In the beginning of the university studies similar factors of motivational approaches were found compared to earlier research (c.f. Hirsto & Tirri, 2009). Of the third year students, 79.9 % reported to be certain of their choice of the curriculum, while in the fifth year 85.7 % were certain. The distribution of the choices in third and fifth year represented very well the distribution of the graduating Masters' of Theology. According to preliminary analysis, experienced spiritual calling is related to the certainty of curriculum choice in the third year of the university studies ($t=2,540$, p In addition to certainty of curriculum choice, also the actual curriculum choices were investigated in relation to motives to start to study theology. Of the motivational approaches in the beginning of the university studies, spiritual calling, a helping orientation, assuring a place to study, other people's influence were significantly related to the curriculum choices students had made in the third year of their theological studies. Also, uncertainty of career choice was significantly related to curriculum choices. In the fifth year spiritual calling and a helping orientation in the beginning of the theology studies were related to curriculum choices in the fifth study-year. Also, in the fifth year, uncertainty of career choice in the beginning of the studies was related to curriculum choices. The contents of the reasons students gave for their curriculum choices were qualitatively analysed and classified. Top level categories were named: calling or certainty, exclusion and other. However, the nature of the explanation differed according to curriculum choices, which students had made. Therefore, the relationships of these curriculum choice bound explanations were investigated further. This revealed interesting significant relationships and variety of the motivational approaches of the students following different curriculum paths. The study path of religion teachers and

pastors seems to be somewhat coherent, but students' in general theological education curriculum seems to have more or less dissonant approach to their studies.

Theoretical and educational significance of the research

This study sheds light to university students study paths in a specific context of theological education. The findings will be discussed in terms of the theoretical background, self-regulation (e.g. Pintrich, 2004; Zimmerman, 2002; Boekaerts & Cascallar, 2006) and curriculum development. Through this empirical starting point, implications are discussed also in terms of more general academic education. This research contributes to the understanding of how motivational approaches in the beginning of university studies may affect the choices later in the study-path. It seems that spiritual calling, which, in case of other curriculum choices except that of becoming a pastor, seem to take a form of unquestioned certainty, plays an important role in certainty of choices during university studies. More generally, results also suggest that there are students trying to progress in their university studies, but who may not have a very clear vision of their goals. If this lack of perspective is persistent, which it seems to be according to these results, this phenomena would need more intensive elaboration in developing higher education curricula.

PAPER PRESENTATION

Achievement Goals Over Time: How Changes in Mastery and Performance-Approach Predict Deep Knowledge

Daniel Belenky, University of Pittsburgh, United States; Timothy Nokes, University of Pittsburgh, United States; Matthew Bernacki, University of Pittsburgh, United States

The current study examines two factors that are critical to understanding the role of achievement goals in classroom learning; how goals change over time and the relation between those goals and what is learned. Students' achievement goals were measured in relation to three exams completed during a Cognitive Psychology lecture course (N = 154). The exams included items that assessed different kinds of knowledge including factual, conceptual, and application based understanding. Performance on the initial exam was predicted by student performance-approach goals, while performance on the third exam was predicted by mastery-approach goals. Moreover, a positive change in mastery-approach goals from Exam 1 to Exam 3 led to increased performance on the third exam, while a positive change in performance-approach goals led to decreased performance. This effect was driven by an advantage for mastery-approach goals on the application-based items. These results indicated that mastery-approach goals may be particularly important for the development of deeper forms of understanding, and that movement towards such goals over the course of a semester may be a pedagogically important aim for instructors.

The relationship between achievement goal orientations and academic performance is mixed (see Linnenbrink-Garcia, Patall, & Tyson, 2008). In some cases, mastery goals predict achievement, while in others, performance goals are better predictors. In the current study, we focus on two factors that may be contributing to the conflicting findings in the literature; the type of knowledge being measured on achievement tests, and how goals change over time. Specifically, we analyzed exam items, differentiating between fact-based, concept-based, or application-based questions. We test the hypothesis that advantages observed for performance-approach goals reflect performance on items that assess a fact-based understanding, while advantages for mastery-approach goals reflect deeper forms of understanding as measured by concept- and application-based items (see Harackiewicz, Barron, Pintrich, Elliot, & Thrash, 2002). Furthermore, we examined how achievement goals change over the course of a semester, and how these changes influence exam performance.

Methodology:

Participants were students in a Cognitive Psychology course at the University of Pittsburgh (N = 154). Students completed questionnaires at four time points throughout the semester; on the first day, before the first exam (5 weeks in), before the second exam (9 weeks), and before the third exam (14 weeks). Questionnaires assessed a range of motivational and self-regulatory variables. For the purposes of this paper, we focus on achievement goals and their relationship to exam performance. We measured mastery-approach, performance-approach, and performance-avoidance goals using three 7-point Likert scale items for each construct (1 = Strongly Disagree, 7 = Strongly Agree) from the Achievement Goal Questionnaire – Revised (Elliot & Murayama, 2008).

For each multiple-choice exam, the percentage of total items correct was calculated to measure overall performance. The items on each exam were analyzed and coded into sub-categories of fact-based, concept-based, or application-based items by two raters ($\kappa = 0.94$, $n = 125$, $p < .05$). Fact-based items assessed the direct recognition of information from the course, concept-based items required students to reason with concepts and theories covered in the course, and application-based items required students to apply knowledge to a given scenario or analyze given information in light of particular concepts or theories.

Findings:

Mean values for each goal score at the first and third exam are given in Table 1. Each construct showed a decrease in endorsement of these goals across time points.

To analyze the effect of achievement goals on Exam 1 performance, the three achievement goal constructs were entered as predictors into a linear regression predicting exam scores. Overall performance was not predicted by any achievement goal. However, when examining the subscales, we found that performance-approach was a marginal predictor of factual and applied item performance ($B = .27, p = .07$ and $B = .28, p = .06$, respectively), performance-avoidance goals negatively predicted performance on the applied items ($B = -.31, p < .05$), and mastery-approach goals did not predict any subscales. In contrast to the first exam, mastery-approach goals predicted performance on the third exam ($B = .25, p < .05$). When looking at subscales, mastery-approach predicted performance for factual and applied ($B = .26, p < .05$ and $B = .31, p < .05$, respectively) and was marginally predictive of performance on conceptual items ($B = .16, p = .10$). Neither performance goal was predictive of subscale scores at Exam 3.

The effect of mastery-approach at the third exam is particularly interesting in light of the fact that, as a whole, the class reported less mastery-approach goals at the third exam than at the first (see Table 1). To examine the effect of this change on an individual basis, we calculated a difference score for each student by subtracting goals at Exam 1 from goals at Exam 3. This resulted in a "change score" value for mastery-approach, performance-approach, and performance-avoidance goals. A negative change score indicates that the student decreased in their endorsement of that particular goal. These change scores were entered into a regression predicting performance on Exam 3. Mastery-approach change scores positively predicted exam performance ($B = .23, p < .05$), while performance-approach change scores negatively predicted exam performance ($B = -.24, p = .05$). Looking at the subscales, we see that performance on applied items is positively predicted by changes in mastery-approach goals ($B = .33, p < .05$), but marginally negatively predicted by changes in performance-approach goals ($B = -.22, p = .08$). Increases in mastery-approach goals promoted deep understanding, while increases in performance-approach goals inhibited the development of such understanding.

Summary:

Exam 1 performance was positively predicted by performance-approach goals but not mastery-approach goals. However, at Exam 3, mastery-approach goals positively predicted performance whereas performance-approach goals did not. Furthermore, changes in these goals over time predicted exam performance. Students who became more mastery-oriented had higher Exam 3 scores, while those who became more performance-approach oriented had lower scores. These changes were especially strong for the applied items that required a deeper understanding of the material.

Theoretical and Educational Significance:

In order to shed light on inconsistent findings in the literature on the relationship between achievement goals and achievement we focused on how student goals change over time and the types of measures used to assess achievement. We found that an increase in mastery-approach goals over time leads to better performance on measures of deeper understanding. In contrast, increases in performance-approach goals were associated with lower performance on such measures. Focusing attention on variation of achievement goals across time and context may improve our conceptualization of how achievement goals positively influence students, and how educators can maximize these benefits.

PAPER PRESENTATION

Longitudinal relationships between achievement goal orientations, well-being and educational choice

Markku Niemivirta, University of Helsinki, Finland; Katariina Salmela-Aro, Helsinki Collegium for Advanced Studies, Finland; Heta Tuominen-Soini, University of Helsinki, Finland

The purpose of this study was to examine the developmental characteristics of secondary school students' achievement goal orientations, and, especially, the relative benefits of adopting either mastery vs. performance-

focused goal orientations in terms of students' subjective well-being. The participants were of 549 secondary school students of whom 176 (42% females) chose the vocational track and 373 (52% females) chose the general academic track after the ninth grade. The design included four measurement points, two before and two after the transition from lower secondary to upper secondary education. All students completed a questionnaire with scales assessing achievement goal orientations, self-esteem, depressive symptoms, and satisfaction with educational choices. Latent growth curves were estimated for each type of achievement goal orientation. Later ratings of self-esteem, depressive symptoms, and satisfaction were regressed on the trajectories of change in achievement goal orientations, while controlling for the effects prior level of self-esteem, frequency of depressive symptoms, and school performance. The results showed some systematic changes in achievement goal orientations over time, which, to some extent, were moderated by the educational context. Changes in achievement goal orientations independently influenced the students' later well-being. The patterning predictive effects showed that positive changes mastery tendencies were related to parallel changes in well-being, whereas increases in performance-focused tendencies, especially in performance-avoidance orientation, were associated with decreases in well-being. The findings of this study contribute to our understanding of the long-term changes in students' academic motivation during the transition from lower secondary to upper secondary education.

Achievement goal orientations refer to individuals' tendencies to strive for certain outcomes and to favor some types of goals over some others. Much of the recent research on achievement goal orientations has focused on their achievement-related antecedents and outcomes (for a review, see Kaplan & Maehr, 2007). Fairly little attention has been paid on the developmental aspects of different orientations and how changes over time in them relate to some personal factors other than achievement, such as subjective well-being. Quite lively debate has also focused on the relative benefits of adopting either mastery tendencies (i.e., striving for gain in competence) vs. performance-related tendencies (i.e., striving for the demonstration of competence), although the criteria for evaluating such adaptiveness have mostly revolved around achievement-related indicators (Midgley, Kaplan, & Middleton, 2001). The main objective of this study was thus to contribute to the current discussions by examining the developmental characteristics of secondary school students' achievement goal orientations, and, especially, whether the striving for some types of goals in the long run proves to be more beneficial in terms of subjective well-being than striving for some other types of goals.

The few studies available addressing the linkage between achievement goal orientations and well-being suggest that tendencies reflecting the strive for self-improvement and growth (i.e., mastery focus) are related to more adaptive socio-emotional functioning and more positive self-evaluations, whereas the tendency to validate and demonstrate one's personal qualities (i.e., performance focus) is associated with adjustment problems and socio-emotional vulnerability (e.g., Sideridis, 2005; Tuominen-Soini, Salmela-Aro, & Niemivirta, 2008). In this study, we expected to find similar relationships between achievement goal orientations and subjective well-being in a longitudinal setting. That is, we assumed that changes over time in different types of achievement goal orientations were predictive of later well-being in such a way that increases in mastery-focused tendencies were associated with higher well-being, and increases in performance-focused tendencies were related to lower future well-being.

The participants were of 549 secondary school students of whom 176 (42% females) chose the vocational track and 373 (52% females) chose the general academic track after the ninth grade. The design included four measurement points, two before and two after the transition from lower secondary to upper secondary education. All students completed a questionnaire with scales assessing different achievement goal orientations (e.g., mastery, performance-approach, and performance-avoidance orientations) and two important aspects of general well-being, self-esteem and depressive symptoms. Also, students' ratings reflecting their satisfaction with their educational choices were assessed at time 4. Within the structural equation modeling framework, latent growth curves were estimated for each type of achievement goal orientation. Later ratings of self-esteem, depressive symptoms, and satisfaction were regressed on the trajectories of change in achievement goal orientations, while controlling for the effects prior level of self-esteem, frequency of depressive symptoms, and school performance.

The results showed an increase in mastery goal orientation over time, whereas no change was detected in performance-approach and performance-avoidance orientations. The trajectories of change were moderated by educational track so that stronger increase in both mastery and performance-approach tendencies were evident for vocational students. When examining the predictive effects of growth trajectories of achievement goal orientations on well-being, the results showed that later self-esteem was predicted by lower initial level of performance-avoidance orientation as well as by increases in mastery orientation and decreases in performance-avoidance orientation. Depressive symptoms were influenced by both prior school performance and increases performance-avoidance orientation. The initial level of mastery orientation as well as increases in mastery orientation and decreases in performance-avoidance orientation had an effect on students' satisfaction with their educational choices.

The findings of this study suggest some systematic changes in achievement goal orientations over time, which, to some extent, are moderated by the educational context (i.e., educational track). Changes in achievement goal orientations also seem to independently influence the students' later well-being. The patterning predictive effects further show that positive changes mastery tendencies appear to be related to parallel changes in well-being, whereas increases in performance-focused tendencies, especially in performance-avoidance orientation seem to contribute to decreases in well-being. The findings of this study add to understanding of the long-term changes in students' academic motivation during the transition from lower secondary to upper secondary education. The results also importantly contribute to the recent debate on the benefits of adopting either mastery-focused or performance-focused achievement goal orientations in school settings.

PAPER PRESENTATION

Mathematics with eyes wide shut: Facing challenges and overcoming barriers

Claudia Ventura, Faculdade de Ciencias e Tecnologia da Universidade Nova de Lisboa, Portugal; Nuno Santos, Escola Secundaria de D. Dinis, Lisboa, Portugal; Margarida Cesar, Universidade de Lisboa, Instituto de Educacao, Portugal

In Portugal, students categorised as presenting Special Educational Needs attend mainstream classes (ME, 2008). Mathematics presents high levels of rejection and low achievement (Céêsar, 2009). Considering mathematics knowledge as socially constructed, giving a meaning is an essential step to access mathematical tools (Vygotsky, 1934/1962). Representing mathematical objects is a barrier blind students experience. Braille writing specific features must be considered when teachers talk about mathematics in classes including blind students (Santos & Céêsar, 2007). They need a thick descriptive discourse and language adapted to Braille writing. In a mainstream classroom teachers must consider the blind student(s) and the non-impaired students, facilitating all students' participation. Communication plays an essential role in students' mathematical knowledge appropriation (Sfard, 2001). Collaborative work can be used as a mediator of students' learning (Céêsar, 2009). This study belongs to the Interaction and Knowledge project whose aims were to study and promote collaborative work in formal educational scenarios. We assume an interpretative approach and an action-research design. The main participants are the students (N=190) from classes including blind students (N=11), two teacher/researchers and a psychologist. The data collection instruments are: observation, questionnaires, documents, informal conversations and students' protocols. Inductive categories emerged from the content analysis (Hamido & Céêsar, 2009). We analyse some examples of students' solving strategies and social interactions illuminating teachers' role in blind students' learning process and the particularities of mathematics Braille. They also illustrate the importance of the communicative processes due to the use of mathematical Braille, particularly differences among blind and non-blind students.

The Salamanca Statement (UNESCO, 1994) symbolises a rupture: changing from the integration into the inclusion paradigm. In the integration paradigm, schools and society looked for students' normalization. After the Salamanca Statement students' characteristics are respected and teachers try to potentiate them (Céêsar & Ainscow, 2006). In the Portuguese curriculum mathematics is a compulsory subject until the 9th grade (14/15-year-olds). It is one of the most selective, as many jobs and university courses ask mathematics as a condition to be admitted (Céêsar, 2009). Failing in this subject puts students' school path and professional life at risk. Mathematics is one of the subjects that more often contribute to early school dropouts. Therefore, it is crucial to promote all students' access to mathematics achievement, particularly blind ones. Mathematics uses abstraction, an ability that is more difficult to develop when students use a symbolic system (Braille) different from the one used by non-impaired students. This is a barrier blind students need to overcome in order to mobilize/develop their mathematical abilities and competencies (Santos & Céêsar, 2007). Communication is also very important to a blind student because s/he does not have access to the information captured through sight. Thus, we need alternative forms of communication that can surpass this problem. A mathematics teacher of a mainstream class with blind student(s) must adapt his/her practices to each student, including the blind one(s). A way to include every student in the mathematical activities is through the promotion of peer social interactions. Social interactions play an important role in students' socio-cognitive and emotional

development (Vygotsky (1934/1962) and in giving students a voice (Wertsch, 1991). Collaborative work in mathematics classes is a way to promote peer and dialogical social interactions (Céêsar, 2009). The problem that originated this research was the difficult inclusion process experienced by many blind students in a mainstream mathematics class. We aim to understand the sort of communication that is established between mathematics teachers and blind students included in mainstream classes, the adaptations that can be observed in the practices developed by teachers and the interactive patterns between students (blinds and non-blind).

The research questions we address are:

- (1) Which are the facilities and the difficulties that blind students experience to have access to the cultural mathematical tools?
- (2) What can be done to facilitate their access to them?

This study is part of Interaction and Knowledge (IK) project. Its main aims were to study and to promote collaborative work in formal educational scenarios, contributing to a more inclusive and intercultural education (Hamido & Céêsar, 2009). This research project lasted 12 years (1994/95 to 2005/06), included 69 mathematics teachers and more than 600 mathematics classes. We focus in those attended by blind students (N=11) included in mainstream schools. We assume an interpretative approach (Denzin, 2002) and developed action-research projects (Mason, 2002). The participants were these blind students (7th to 12th grades – 12 to 18 years old), their classmates (N=190), their mathematics teachers, a psychologist and significant others (colleagues, friends, families, other educational agents).

During the first week of the school year (September), students answered to a questionnaire, a task inspired in projective techniques and an instrument to evaluate abilities and competencies. They also answered two other questionnaires in the begging of the second term (January) and the end of the school year (June). Participant observation (registered in teacher/researchers' diaries, audio/video taped, photos), informal conversation, documents and students' protocols were collected during all school year. Data treatment and analysis is based in a narrative content analysis (Clandinin & Connelly, 1998) from which inductive categories emerged (Céêsar, 2009) illuminating empirical evidence.

We analyse some examples that illuminate teachers' adaptations to practices and to the communication with blind students. We also present some examples of solving strategies and mathematical thinking, discussing the particularities of the Braille writing. This analysis illuminated that there were complements of verbal information to respect the blind students' characteristics. Some complementary information was presented through movement, touch and materials adapted to befit their needs. But teachers also performed some adaptations to the tasks to allow the blind students to participate in the same mathematical activities as their peers. Thus, the results illuminate how dialogical social interactions can contribute to a more inclusive mathematics education and facilitate blind students' access to the cultural tools of mathematics.

PAPER PRESENTATION

The relationship between naming-speed and spelling in dyslexia

Erlijn van Genuchten, Knowledge Media Research Center, Germany; P. C-H. Cheng, School of Informatics, University of Sussex, United Kingdom; Paul A. Kirschner, Open Universiteit, Netherlands; Paul Leseman, Utrecht University, Netherlands

Literature about dyslexia proposes two competing theories. The phonological deficit theory holds that people with dyslexia have problems with their phonological representations, whereas the double deficit theory holds that people with dyslexia show an additional naming-speed deficit that is claimed to be equally important in causing reading problems. Research on the relationship between naming-speed and reading has shown that reading problems are related to the commonalities between phonological processing and naming-speed, which supports the phonological deficit theory. However, research on the relationship between naming-speed and spelling has shown that naming-speed remains a significant predictor for spelling when phonological problems are controlled, which supports the double deficit theory. A problem with studies relating naming-speed to spelling is that they use the standard naming-speed test used in reading research. In this test, individuals have to verbally name letters, instead of presenting them graphically. Also, this test does not distinguish between information processing speed and pronunciation speed. To this end, we implemented an adapted naming-speed test — measuring the speed of retrieving a letter from memory during writing — to investigate the relationship between naming-speed and spelling. The results confirm previous findings that naming-speed and spelling are unrelated. Our findings imply that future studies should use adapted naming-speed tests to shed light on why the phonological deficit theory explains the relationship between naming-speed and reading and the double deficit theory the relationship between naming-speed and spelling.

Literature about dyslexia proposes two competing theories. One, the phonological deficit theory, holds that people with dyslexia have problems with their phonological representations affecting performance on any task requiring phonological processing (Pennington, Cardoso-Martins, Green, & Lefly, 2001). The other, the double deficit theory, holds that people with dyslexia show an additional naming-speed deficit that is claimed to be equally important in causing reading problems (Vaessen, Gerretsen, & Blomert, 2009).

The phonological deficit is defined as difficulties in storing and/or retrieving words and in processing information in working memory, whereas the naming-speed deficit is defined as the inability to rapidly retrieve phonological codes from memory (Vellutino, Fletcher, Snowling, & Scanlon, 2004). Although many studies have shown that people with dyslexia indeed have phonological processing problems (e.g., Pennington et al.), it is still unclear whether naming-speed is a separate problem or a problem caused by phonological processing weaknesses.

Research on the relationship between naming-speed and reading has shown that reading problems are related to the commonalities between phonological processing and naming-speed (e.g., Schatschneider, Carlson, Francis, Foorman, & Fletcher, 2002), which supports the phonological deficit theory. However, research on the relationship between naming-speed and spelling has shown that naming-speed remains a significant predictor for spelling when phonological problems are controlled (e.g., Savage, Pillay, & Melidona, 2008), which supports the double deficit theory. A problem with studies relating naming-speed to spelling is that they use the standard naming-speed test used in reading research. This test measures the time individuals take to encode and verbally name a series of letters (Denckla & Rudel, 1976). In contrast, letters are decoded and presented graphically during writing. Another problem is that the time needed to utter the name of a letter is included in the measured time. However, as people with dyslexia have problems with rapid naming, it is more relevant to examine how long they take to retrieve a letter name from memory. To this end, we implemented an adapted naming-speed test—measuring the speed of retrieving a letter from memory during writing—to reinvestigate the relationship between naming-speed and spelling. **Method** Participants were 95 Dutch children (Mage = 8.28 years, SD = .64), namely 29 grade 3 children with dyslexia (DYS), 33 grade 3 chronologically age matched (CA) children without dyslexia, and 33 grade 2 reading age matched children (RA) without dyslexia. Children wrote four types of sentences (N = 24) from memory. In familiar sentences (e.g., Have go hungry), syntactic, semantic, and phonologic support facilitated remembering. In jumbled sentences, syntactic support was removed by presenting words in random order (e.g., You the dog). In sentences containing language-like non-words (e.g., Rummer hoat barden), semantic support was removed by presenting non-existing words that sounded Dutch.

Finally, in sentences containing language-unlike non-words (e.g., Knuk greupeg), phonological support was removed by presenting non-existing words that did not sound Dutch. Children also wrote their first names, which served as a writing baseline. To evoke pauses between letters, children wrote sentences on a piece of paper attached to a graphics tablet containing horizontal rows of rectangles. They wrote one letter in each rectangle (Figure 1). Naming-speed was measured as pause lengths by gauging the time that the pen was lifted from the paper between writing two consecutive letters.

Figure 1. Example sentence. After the experiment, we counted the number of phonological spelling errors. These errors were marked when a word sounded completely different than the stimulus (e.g., 'knuf' instead of 'knuk'). Results We predicted naming-speed or the number of phonological spelling errors with type of sentence, group and writing baseline simultaneously in a regression analysis. This analysis revealed that CA children exhibited shorter pause lengths and made fewer phonological spelling errors than RA and DYS children. RA and DYS children did not differ in pause lengths; however DYS children made more spelling errors than RA children. A second regression analysis testing whether pause length mediated the effect of group on spelling errors yielded no significant results.

Discussion

The double deficit theory was confirmed by two findings. First, DYS children lagged behind in their spelling development compared with their peers; this disadvantage was clearer for phonological processing than for naming-speed problems. This supports the double deficit theory as a similar pattern would be expected for similar deficits. Second, the finding that naming-speed did not mediate the effect of group on spelling errors also confirmed that the naming-speed and phonological processing deficits are independent. These results are in line with previous studies on the relationship between naming-speed and spelling. These findings imply that future studies should use adapted naming-speed tests?measuring time to retrieve a name from memory instead of total performance time?to shed light on why the phonological deficit theory explains the relationship between naming-speed and reading and the double deficit theory the relationship between naming-speed and spelling.

PAPER PRESENTATION

Dyslectic trainee teachers' views of their educational trajectory and their future vocational role

Lena Ivarsson, Mid Sweden University, Sweden; Ulla Damber, Mid Sweden University, Sweden

The objectives of this study was to explore how Swedish dyslectic trainee teachers view their past educational trajectory, their present studying situation, their adjustment to university studies, and their future vocational role. To get an inside perspective of the students' perceptions, in-depth interviews were chosen as method of inquiry. As the conditions for dyslectic students in school have changed according to different policy documents over time a life history perspective was employed in the interviews. This was made in order to get a full description both of the individual experiences and the conditions provided by the school environment. Even though all ten students have a diagnosis of dyslexia, a majority of them were not diagnosed until they were in upper secondary school or even at the university. One major finding was that no extra support was given until the diagnoses were made. The students perceived that their university studies required rigorous planning and lots of time, and they claimed that the compensatory support they had been given was crucial to them to meet the academic demands. In describing their Future Time Perspective the students emphasized their ability to understand and help children with special needs.

This was a major driving force for them to apply to become trainee teachers. A major implication of these findings is that dyslectic children are not identified so that remedial assistance can be brought in as early as possible. Secondly, these students' capacities and strengths should earn more attention both in practice and research.

The overarching objectives of this study were to explore how Swedish dyslectic trainee teachers view their past educational trajectory, their present studying situation, their adjustment to university studies, and their future vocational role. The study was conducted in Sweden at a small university, predominantly carrying out distance education. A substantial part of the student body has a working-class background. The informants, all women, were varying in age from twenty to fifty. The distribution of the sexes reflects the fact that the majority of the trainee students are women. To get an inside perspective of the students' perceptions, in-depth interviews were chosen as method of inquiry. The student counselor, who was the contact person for dyslectic students, distributed invitations to the students to participate in the study. This procedure was chosen to guarantee the students' anonymity in case they rejected the invitation. In order to get a picture of the compensatory support the students were offered at the university, the student counselor was also interviewed. The theoretical framework is based on a social cultural view of the individual and his/her learning (Wertsch, del Rio, & Alvarez, 1995).

We aimed to employ a broad perspective on the students' life situations, including their social, cultural, and historical background, and not only their clinical background. The social, cultural, and historical perspective also encompasses the view of learning employed in the study. As the conditions for dyslectic students in school have changed according to different policy documents over time, a life history perspective was employed in the interviews (Goodson, 1994), together with a Future Time Perspective (FTP), as FTP is an important predictor of school investment and academic success (Peetsma, 2000). A simplified version of the Zimbardo time perspective inventory was employed in the student interviews (Zimbardo & Boyd, 1999). The life history perspective was chosen in order to get an extended description both of the individual experiences and the conditions provided by the school environment. Even though all ten students have a diagnosis of dyslexia, a majority of them were not diagnosed until they were in upper secondary school or even at the university. In Sweden children are seldom diagnosed with dyslexia in elementary school. It seems like the students were able to handle the rather simple texts, often fictional, used in early reading instruction. In the students' narratives it is clear that the problems with reading got more apparent when they encountered more abstract and complex non-fictional texts in upper secondary school and, above all, at the university level.

Most students were diagnosed with dyslexia as upper secondary school students or as university students. The student narratives revealed that the need for support was clearly manifested in upper secondary school, but no support was offered. One major finding was that no extra support was given until the diagnoses were made. Even those students, who had an earlier diagnosis, were dependent on the help each individual teacher could or would offer. Some students reported that their self-esteem suffered a lot as they linked their reading problems to a view of themselves as "being stupid". In particular, for those students, the diagnosis of dyslexia was a relief. At university level the students perceived that their studies required rigorous planning, a lot of time, and many hours of reading. They claimed that the compensatory support they had been given, was crucial to them to meet the academic demands. The compensatory actions will be described in the presentation. In describing their Future Time Perspective the students emphasized their ability to understand and help children with special needs. This was a major driving force for them to apply to become trainee teachers. Firstly, a major implication of these findings is that dyslectic children are not identified so that remedial assistance can be set in as early as possible. Secondly, it is obvious that the condition of dyslexia, in these students, is not only linked to the problems associated with reading, but also to a strong Future Time Perspective and ability to large investments in their studies. Our conclusion is that these students' capacities and strengths should earn more attention both in practice and research.

PAPER PRESENTATION

Academic self concept in children with special educational needs attending different school types

Dietmar Grube, University of Oldenburg, Germany; Lieselotte Scheewe, University of Bremen, Germany;

Julia Nicklaussen, Carl-von-Ossietzky Universitat Oldenburg, Germany; Susanne Mayer, Carl von Ossietzky University of Oldenburg, Germany

Some children with a mild intellectual disability or with socio-emotional problems visit classes at special schools, some others are integrated within classes in regular elementary schools. The academic self-concept is an important variable for life-long learning. From the theoretical view of the big-fish-little-pond-effect (Marsh, 1987) lower self-concept scores can be predicted in children that are integrated in classes at regular schools than in children instructed in special classes.

The present study is aimed at testing this hypothesis. Self-concept and other school related variables were collected from 13 children attending special classes and from 13 children attending regular classes. All children had been diagnosed as needing special educational help. The children attending schools in the rural regions of Germany were matched for age (about 9 years) and sex. For reasons of statistical control individual reading, arithmetic and working memory were assessed. Each child completed a questionnaire regarding emotional and social school experience ("Fragebogen zur Erfassung emotionaler und sozialer Schulerfahrungen", FEES 1-2; Rauer & Schuck, 2004). The groups of children differed significantly regarding academic self-concept, attitude toward school and enjoyment to learning with children educated in special classes showing more advantageous values than children integrated within regular elementary schools. An analysis of covariance showed that the significant differences were saved after controlling cognitive variables.

Findings

Show that self-concept of children with special needs is at risk if the children are schooled within regular schools. A disadvantageous self-concept seems to reduce the attitude toward school and the enjoyment to learning.

Children who fail to profit from regular instruction at school in the long term may be categorized as children with special educational needs. Some children with a mild intellectual disability or with socio-emotional problems visit classes at special schools, some others are integrated within classes in regular elementary schools. In former times, special classes were arranged in order to give special instruction to children with special needs and in order to save them from learning standards they can't reach. Nowadays, directed by the Convention on the Rights of Persons with Disabilities (2006), more and more children with special needs receive their special education while attending regular schools.

Children with special educational needs should be encouraged regarding both, cognitive and socio-emotional aspects. On the socio-emotional side, the academic self-concept is an important variable. In this theoretical context the well known big-fish-little-pond-effect (Marsh, 1987) predicts a disadvantageous self-concept in children with classmates whose mean capability is much higher than their own. Therefore one could predict lower self-concept scores in children that are integrated in classes at regular schools than in children instructed in special classes. On the other side, teachers of regular classes that integrate children with special needs should be well trained and prepared to be conscious of the big-fish-little-pond effect and to fight against it. From this point of view one should predict no differences between the two groups of children educated in different contexts.

The present study is aimed at investigating the self-concept of children with special educational needs attending special classes compared to children attending classes in regular schools. Self-concept and other school related variables were collected from 13 children attending special classes (four girls, nine boys, mean age = 9;0 years, SD = 0;3) and from 13 children attending regular classes (four girls, nine boys, mean age = 9;1 years, SD = 0;4). All children had been diagnosed as needing special educational help. The children attending schools in the rural regions of Germany were matched for age and sex. For reasons of statistical control individual reading and arithmetical skills as well as working memory were assessed. Each child completed a questionnaire regarding emotional and social school experience ("Fragebogen zur Erfassung emotionaler und sozialer Schulerfahrungen", FEES 1-2; Rauer & Schuck, 2004) that gives information about the following seven variables: social integration, class climate, academic self-concept, attitude toward school, effort tendency, enjoyment to learning, feeling to be accepted.

Simple t-tests ($\alpha = .05$) did not show significant differences between both groups of children regarding reading and arithmetical skills and working memory. However the groups of children differed significantly regarding academic self-concept ($d = 1.04$), attitude toward school ($d = 0.92$) and enjoyment to learning ($d = 0.99$) with children educated in special classes showing more advantageous values than children integrated within regular elementary schools. For the other socio-emotional variables analyses did not show any significant differences. Because there were tendencies toward better cognitive skills in children attending special classes an additional analysis of covariance was carried out. This analysis showed that the significant differences found for socio-emotional variables were also significant after controlling reading skills, arithmetical skills and working memory.

These findings show that the self-concept of children with special educational needs is at risk if the children are schooled within regular elementary schools. A disadvantageous self-concept seems to reduce the attitude toward school and the enjoyment to learning. Consequently, teachers instructing children with special needs within regular schools have to take the risk for the self-concept of the children into account. Educational research has to yield further knowledge and schools of education have to impart the knowledge about how to save the self-concept of students from being damaged by the context of more capable peers.

PAPER PRESENTATION

The role of text production processes in the development of understanding through writing

Veerle Baaijen, Center for Language and Cognition Groningen, Netherlands; David Galbraith, Staffordshire University, United Kingdom; Kees de Glopper, Faculty of Arts, University of Groningen, Netherlands

Writing is often used as a tool for learning in schools. Current theories of writing, however, have different conceptions of the processes responsible for its epistemic effects. The knowledge-transforming model (Bereiter and Scardamalia, 1987) attributes it to deliberate planning designed to satisfy rhetorical goals. By contrast, the dual-process model (Galbraith, 2009) claims that it depends on the spontaneous formulation of thought during dispositionally-guided text production. Two groups of writers - high self-monitors, whose writing is assumed to be directed towards rhetorical goals, and low self-monitors, whose writing is assumed to be dispositionally-guided - were asked to write an article for the university newspaper. Half the participants were asked to make an outline before writing (outline planning); the other half were asked to sum up their main point before writing (synthetic planning). All participants were asked to rate their understanding of the topic before and after writing, and, in order to assess the extent to which content was modified during text production, keystroke logs were collected. The results are broadly compatible with the dual-process model: (i) writers reported significantly more development of understanding after synthetic than after outline planned writing; (ii) low self-monitors writing synthetically planned text showed much higher levels of text modification during writing; (iii) developments of understanding within the synthetic planning condition were significantly related to the extent of text modification during writing. Alternative explanations for the findings, and their implications for designing school writing tasks, will be discussed.

Writing is often used as a tool for learning in schools. However, there are contrasting conceptions about what is responsible for the epistemic effect of writing. Problem solving models of writing (e.g. Bereiter and Scardamalia, 1987) attribute the development of understanding through writing to deliberate planning designed to satisfy rhetorical goals. By contrast, Galbraith (2009) claims that the development of understanding depends on the extent to which text production is dispositionally driven. This paper focuses on the fundamentally different role that these two theories attribute to text production processes. For the problem solving models of writing, text production is a passive process of translating thoughts into words, whereas the dual process model (Galbraith, 2009) suggests that text production is an active knowledge constituting process in its own right. 42 high self-monitors (whose writing is assumed to be directed towards rhetorical goals) and 42 low self-monitors (whose writing is assumed to be dispositionally driven) were asked to plan and write an article for the university newspaper. Half the participants were asked to make an outline before writing (planned text production) while the other half were asked to write down a single sentence summing up their overall opinion (non-planned text production). We used the latter as a control planning condition, which we defined as synthetic planning.

To assess the development of understanding, participants were asked to list ideas and to rate their understanding of the topic both before and after writing. To assess the extent to which content was modified during text production, keystroke logs were collected during writing (Leijten & Van Waes, 2006). In order to capture text production processes we used a simple indicator of content modification during text production, which we will label as the text modification index. The text modification index is the number of process words registered by Inputlog as a proportion of words in the final text. This index is taken as the extent to which text is modified during writing. Because only the dual process model attributes an active role to text production processes we will take the perspective of the dual process model to state the predictions. If the dual process model is right then the text modification index should be at a maximum when low self-monitors write synthetically planned texts, since it is assumed that low self-monitors' writing is dispositionally driven and that outline planning reduces the extent to which text production is spontaneous. Furthermore, if the dual process model is right, high levels of text modification should also be associated with increases in subjective understanding.

This experiment showed three important results. First, writers reported significantly more development of understanding after synthetic than after outline-planned writing. Secondly, low self-monitors writing synthetically planned text showed much higher levels of text modification during writing than the high self-monitors writing outline planned texts. Third, developments of understanding within the synthetic planning condition were significantly related to the extent of text modification during writing. Taken together, the latter two results suggest that dispositionally-driven (i.e. low self-monitors') writing leads to more modification of thought during text production than writing that is directed towards rhetorical goals (high self-monitors), and this is associated with the development of writers' subjective understanding. This effect is reduced when writing is outline planned. These results are, therefore, compatible with the main claims of Galbraith's dual process model. However, a key question that remains is the nature of the process by which text modification occurs during writing. Is it a consequence of the spontaneous formulation of thought in language, or of a more deliberate planning and rhetorical evaluation of sentences as they

are produced? In order to examine this, a further, more detailed analysis of the key-stroke logging data is currently in progress. To date, this analysis has supported the assumption that the text modification index is a valid measure of differences in the number and nature of production and revision phases during writing. More detailed analyses of these findings will be reported in the paper, in addition to the data described above. These results have potentially important implications for the way that writing is taught in schools. Outline planning is one of the most common writing strategies taught in schools, and this is often accompanied by a focus on the rhetorical goals of different forms of writing. Our results suggest that, at least so far as learning is concerned, more exploratory, less structured forms of writing, may be equally important.

PAPER PRESENTATION

Bursts of written language production increase across the initial years of schooling

Rui Alexandre Alves, Universidade do Porto, Portugal; Ilda Jesus, Universidade do Porto, Portugal

Writers compose in bursts, that is, texts are produced by adding up stretches of words, which in adults have an average length of about nine words (Kaufer, Hayes, & Flower, 1986). How do writers progress to achieve this length? Do children readily start by adding up segments of about nine words? Likely not. Here we report a study conducted with Portuguese children that we set up to find if burst length develops throughout the initial four years of schooling. To test this, we formed groups of first, second, third, and fourth graders ($N = 166$). The children handwrote narratives (elicited by a cartoon like drawing) into a digitizing tablet that recorded pauses and bursts. Regarding pauses, we found that its duration decreased from 1st to 4th grade. Regarding bursts, we found a steady increase in burst length from 1st to 4th grade, the average burst size for the four groups were, respectively: 1.84, 3.53, 5.26, and 7.86 words. This result shows for the first time that burst length heightens during the initial years of schooling. Overall, across grades the picture that emerges from this study is one of writing becoming progressively more efficient, as reflected by decreasing pause duration, and increased burst length. These results are of educational relevance, because online measures of writing, such as pauses and bursts, can be thought as markers of writing efficiency, thus teaching us more about identifying and promoting writing skills in the initial years of schooling.

Writers compose in bursts, that is, texts are produced by adding up stretches of words, which in adults have an average length of about nine words (Kaufer, Hayes, & Flower, 1986). How do writers progress to achieve this length? Do children readily start by adding up segments of about nine words? Likely not, because several studies have already shown that in adults burst length is affected by several factors including domain expertise (Kaufer et al., 1986), language skill (Chenoweth & Hayes, 2001), available working memory capacity (Chenoweth & Hayes, 2003), and transcription skill (Alves, Castro, Sousa, & Stromqvist, 2007; Alves, Olive & Castro, 2010). Since many of these skills show developmental trends with age and schooling, it is likely that in children they might contribute to a steady progression of burst length. Nevertheless, bursts of written language production have been seldom studied in children (but see, Alves, Branco, Castro, & Olive, in press), and this topic is unexplored. Here we report a study conducted with Portuguese children that we set up to find if burst length develops throughout the initial four years of schooling.

The first scientific report that writers compose in bursts was made by Kaufer et al. (1986). They compared expert to novice writers, and showed that the experts had larger bursts and wrote generally better texts. For many years this topic of research was overlooked, but has recently seen a handful of studies. Chenoweth and Hayes (2001) compared undergraduates writing two texts, one in their native language (L1), the other in their second language (L2). As predicted, they found that writers were more fluent and had larger bursts in L1 than in L2. Also in a sample of adult writers, Chenoweth and Hayes (2003) have further shown that reducing verbal working memory capacity by articulatory suppression (saying “tap, tap, tap...” to a metronome) decreased both writing fluency and burst length. Two recent studies by Alves and colleagues have argued that automatizing transcription leads to larger bursts. Alves et al. (2007) asked low and high skilled typists to compose written narratives from a set of pictures. They found that the later group used larger bursts. In an experiment, Alves et al. (2010), randomly assigned undergraduates to one of four conditions resulting from the crossing of output modality (handwriting vs. typing) and transcription skill (low vs. high). They have shown that, irrespective of modality, the high skilled groups composed in larger bursts.

All the skills just discussed have typical progresses during the first years of schooling, thus it is reasonable to expect that they might contribute to more efficient bursts from first to fourth grade. To test this, we formed groups of first, second, third, and fourth graders. The mean ages, size of the groups and gender distributions were, respectively, as follows: $M = 6.4$ years old, $n = 30$, 20 girls; $M = 7.5$ years old, $n = 47$, 20 girls; $M = 8.4$ years old, $n = 48$, 24 girls; and $M = 9.5$ years old, $n = 41$, 24 girls. These groups were asked to write a narrative from a simple line drawing depicting a child strolling with a balloon. The children handwrote the stories into a digitizing tablet, that was controlled by an E-Prime script programmed to measure pauses and bursts of language production.

Two-way Gender X Grade ANOVAs were computed on the means of pause duration and burst length. Regarding pause duration, main effects of both gender, $F(1, 158) = 5.42, p < .05, \eta^2 = .03$, and grade, $F(3, 158) = 7.71, p < .01, \eta^2 = .13$, were found. No interaction was found in this analysis. Girls made shorter pauses than boys. Pause duration decreased from 1st to 4th grades, which is compatible with more efficient composing processes. Regarding burst length, main effects of gender $F(1, 158) = 7.70, p < .01, \eta^2 = .05$, and grade, $F(3, 158) = 40.15, p < .01, \eta^2 = .43$, were found. Also, the interaction between gender and grade was significant, $F(3, 158) = 4.22, p < .01, \eta^2 = .07$. While there were no gender differences in the initial two years of schooling, girls in the 3rd and 4th grade showed larger bursts than boys. A similar gender advantage has been reported before in fourth graders (Alves et al., in press), and seems to be accounted by an early advantage of girls in transcription skills (Berninger & Fuller, 1992). As expected, a steady increase was found in burst length from 1st to 4th grade, the average burst size for the four groups were, respectively: 1.84, 3.53, 5.26, and 7.86 words. This result shows for the first time that burst length increases during the first years of schooling. Overall, across grades the picture that emerges from this study is one of writing becoming progressively more efficient, as reflected in decreasing pause duration, and increasing burst length. These results are of educational relevance, because online measures of writing, such as the one studied here, can be thought as markers of writing efficiency, thus teaching us more about identifying and promoting writing skills in the initial years of schooling.

PAPER PRESENTATION

Instruction as Mediated Practice: a critical analysis of an intervention study

Susan Jones, Exeter University, United Kingdom; Debra Myhill, Exeter University, United Kingdom

Abstract

This paper will present qualitative findings from a nationally-funded study measuring the impact of contextualized grammar teaching. This study was designed in response to calls for a Randomised Control Trial to establish 'if grammar teaching works', but the trial itself was embedded within a qualitative framework. The focus of this paper is the qualitative data, including teacher interviews and observation data. Both the observations and the interviews were coded using a grounded approach employing NVIVO software to facilitate the coding process. The RCT revealed a positive effect of 1.53 for those classes being taught explicit grammar. However the classroom observations and interviews with the teachers reveal that the pedagogic materials used in the intervention were mediated differently by different teachers and key themes informing these differences were linguistic subject knowledge and beliefs about the value of explicit grammar teaching. This presentation seeks to show the different and nuanced ways in which an intervention shown to be effective, is realised in the classroom context.

Introduction

The study from which this data is drawn aimed to measure the impact of contextualized grammar teaching. The term 'contextualized' was used to indicate that grammar features were taught at the point of writing, as a set of linguistic choices the students might employ for purposeful rhetorical reasons. The research took place against a contested background regarding the value of explicit teaching of grammar (Gordon 2005). As a consequence of this debate there had been calls for a Randomised Control Trial to establish empirically 'if grammar teaching works' (Andrews et al 2006) This study employed an RCT but embedded the trial within a qualitative framework. It is this qualitative data that reveals that while there was a positive effect for those classes being taught explicit grammar, the pedagogic

materials were mediated differently by different teachers. Thus it is argued that a simple 'what works' approach to educational research misrepresents the complexity of classroom contexts; the aim here is to reveal some of this complexity through a presentation of the findings from the teacher interviews and classroom observations.

Methodology

32 schools were recruited and randomly assigned to intervention and comparison groups. Both groups were taught three types of writing, Fictional Narrative, Argument, and Poetry Writing, through the year, employing schemes of work designed by the research team. In both conditions the learning focus, period of study, resources and learning objectives were the same; however, the intervention group received detailed lesson plans and a day's training in their use and a pedagogic rationale for the teaching. This rationale was informed by a view of grammar teaching that promoted the exercise of informed choices regarding the multiple possibilities of linguistic expression, rather than the teaching of grammar knowledge for its own sake. The comparison group received medium term plans but no pedagogic support or training and taught in their usual manner. Both groups completed pre and post test writing assessments which were scored by an independent organization responsible for marking the National Key Stage tests in the UK. However informed by a belief that 'to undertake a trial of an educational or social intervention without an embedded qualitative process evaluation would be to treat the intervention as a black box, with no information on how it worked, how it could be improved, or what the crucial components of the intervention were.' Moore, Graham and Diamond (2003) the RCT was embedded within a qualitative design. The qualitative data included teacher and student interviews, observation data and examples of student writing. Contextual data relating to individual teachers such as length of service, academic background and linguistic subject knowledge, together with the demographics of the schools were also collected.

Findings

The headline findings of the study indicated a positive effect size of 1.53 for the intervention group. However, the RCT does not provide a simple answer to the question 'does grammar teaching work.' Embedded within the data are the complexities of the classroom context and the differential ways by which the schemes of work were taught and understood. Both the observations and the interview analysis reveal teachers adapting the schemes of work to accommodate either the teachers' own practice and approach, or to avoid areas that challenged their own subject knowledge. In the interviews the teachers frequently air their own concerns about their lack of linguistic subject knowledge. The teachers also reveal their own beliefs about students' ability to engage with grammatical concepts and the pedagogic decisions that resulted from these beliefs. More positively however, there are also examples of teachers being surprised by unexpected outcomes, experimenting with linguistic possibilities and making connections between the schemes of work and pedagogic practice.

Conclusion

While the headline findings indicate the efficacy of contextualized grammar teaching, the qualitative data reveals that this is mediated in different ways by different teachers. The effectiveness of the teacher is informed by a complex set of understandings and skills of which subject knowledge is only part of the equation (Phelps and Shilling 2004). Schulman (1986) speaks of pedagogic content knowledge as the integration of subject knowledge with pedagogy such that the teacher needs to translate what they know into a form that can be taught to others. What is revealed in this data is the struggle to make this translation. At the same time teaching as a profession is the focus of competing discourses whereby both what is taught and how it is taught is a contested agenda frequently aired in professional, research and social contexts. The place of grammar; the role of the teacher and the purpose of writing instruction have all been subject to significant pedagogic shifts. This ranges from progressive approaches to a more prescriptive skills-based curriculum and more recently, attempts to reduce centralised strategy making, returning autonomy to teachers and schools. This shifting pattern and the tensions created are also articulated by these teachers and visible in their pedagogic decision making. This presentation seeks to show the different and nuanced ways in which an intervention shown to be effective, is realised in the classroom context.

PAPER PRESENTATION

A new perspective into writing regulation: Regulation Episodes in expert research article writing

Anna Inesta, ESADE Business School, Spain; Montserrat Castello, Universitat Ramon Llull, Spain

The present study tests a new unit of analysis, the Regulation Episode, with the objective of identifying patterns in the writing regulation activities implemented by 2 expert writers while producing a research article in Spanish as their L1 in ecological conditions. Qualitative analysis of video-recorded writing sessions (Writer 1: 660 hours in 11 writing sessions; Writer 2: 1016 hours in 12 writing sessions), all produced drafts (Writer 1: 14; Writer 2: 13) and writing diaries (Writer 1: 11; Writer 2: 15) showed that Regulation Episodes took place along the writing processes. Two morphological factors were found to characterize Regulation Episodes: explicitness/implicitness (whether or not Episodes appeared after writers' challenge declaration) and continuity/discontinuity (whether or not Episodes required more than one session to solve the challenge). Also, explicit Episodes focused on molar challenges while implicit episodes focused on local, especially those related to the construction of their authorial voice.

We understand by Regulation Episode the sequences of actions that authors strategically implement with the objective of solving a difficulty or challenge identified during the writing process. We expected that this unit of analysis would allow us to approach the regulation of a challenging task such as research article (RA) writing in a comprehensive way and find meaningful writing strategy patterns in ecological conditions.

Participants were two experienced researchers in the field of psychology, who decided to write a RA in Spanish as their academic writing L1[1] in co-authorship conditions. For the purpose of research, Writer 1 and Writer 2 accepted to work separately on the whole article to compare their versions and negotiate a joined one for submission. Writer 1 devoted 660 hours distributed in 11 sessions to write the RA while Writer 2 devoted 1016 hours distributed in 12 writing sessions.

Two independent judges participated in the categorization of the data at two different levels of analysis. Macro-level analysis involved distinguishing the objectives, challenges, solutions as declared in the writing diaries participants were asked to fill in for every writing session, as well as in the process and retrospective interviews. Micro-level analysis, on the other hand, involved analyzing the transcripts of the researchers' video-recorded writing activity (for each of the writing sessions) to identify the actions implemented while working on the RA as well as infer the intentionality underlying these actions.

Results obtained through macro-analysis confirmed the existence of Explicit REs in the writing process of both participants, which were found to be either continuous (challenge and solutions are cited and implemented in one same writing session) or discontinuous (challenge and solutions are cited and implemented in different writing sessions). Finally, micro-level analysis showed evidence of intentional challenge resolution that had not been explicitly identified by the writers. We considered this to be evidence of implicit Regulation Episodes, which we defined as those sequences of actions of at least 10 bursts[2], some of which are aimed at reformulating or adjusting various elements of the sentence, showing an intention to address a challenge, despite not having made any explicit reference to it during the writing process. Examples of these two kinds of Regulation Episodes will be shown in the session.

[1] In the context of the study there are two official languages, Spanish and Catalan, and while the writers considered Catalan to be their first language, they considered Spanish to be their first language for academic writing purposes.

[2] We use the unit of burst in the same way as Chenoweth & Hayes (2001, 2003) or Beare & Bourdages (2007).

PAPER PRESENTATION

Professional Development through Reflection. A Video and Interview based Analysis.

Corinne Wyss, Educational University Zurich, Switzerland

The conventional Universities of Teacher Education in Switzerland, as well as in the surrounding countries are in a changing phase. Teacher education is part of a critical and controversial discussion and new methods and criteria for teacher education are being looked for. With the definition of standards, the quality of teacher education and the teaching competencies of the students should be secured.

One outcome of these discussions about teacher education and professional career is the image of the teacher as "reflective practitioner". The reflecting competency of a teacher is assumed to be an important factor for professional learning and development. Further more, it is the basis for teaching progression and qualitative instruction. But, there is little known about the reflecting competency of teachers and their reflecting practices.

This study tries to find some evidence by questioning novice and expert teachers with different methods and instruments. The analysis is proceeding on the basis of videotaped lessons which are taken at the beginning and at the end of the job entry phase. The longitudinal study reveals how the reflecting competencies are changing in the first year on the job. The coeval study identifies differences between the novice teachers and the expert teachers.

Affiliation

This paper is written within a national project of the Universities of Teachers Education of St. Gallen and Zürich called "Assessing Standards of Teaching Competency in Initial Teacher Training and in the Job Entry Phase".

PAPER PRESENTATION

Reflecting on Reasoning by Studying Videos

Carolyn Maher, Rutgers University, United States; Cindy Hmelo-Silver, Rutgers University, United States; Marjory Palius, Rutgers University, United States; Robert Sigley, Rutgers University, United States

This study examines the features identified by teachers studying videos of children's mathematical reasoning in an online environment. Analysis of small group discourse about the videos indicate that teachers related the video to their own and classmates problem solving, identified connections to other videos, indicated the enjoyment of studying the videos, and related the videos to opportunities to improve their own teaching. Also, teachers made key connections of the videos to assigned and non-assigned readings. Significant findings are (1) that the video offered a context to discuss the undiscovered potential for reasoning in children and (2) that assigned and other readings were introduced by teachers to support the ideas that were offered.

Aims:

When learning is viewed as a process in a social context, it is crucial to consider ways in which technology influences how students engage in building new knowledge (Collins & Halverson, 2009; Peters & Slotta, 2010). Researchers have argued that technology can serve as cognitive and metacognitive tools that extend classroom experiences beyond the physical classroom to enable learning in virtual spaces (Azevedo, 2005; Lajoie & Derry, 1993). The view that such tools can change the nature of teaching and learning as students enable new forms of activity requires study. It is important to understand how learners develop and deepen their understanding through interactions with each other and with computer tools. Asynchronous discussions offer opportunities to students to be more reflective than they might be in face-to-face groups that call for immediate feedback. They also provide instructors a window into the development and extension of knowledge, offering formative assessment and facilitation of multiple groups (Andriessen, 2006; Bonk et al., 1998). It is claimed that student reflection about their learning is essential in order think about the broader contexts in which they might apply their knowledge (Etkina et al., 2010; Salomon & Perkins, 1989). Opportunities to reflect and revisit ideas, and discuss them within a community of learners, have shown to be especially powerful in the development of mathematical reasoning (XXX, 2010). Blending asynchronous online discussion with access to electronic resources, particularly videos, suggests a potent model for catalyzing learning among mathematics teachers.

The Study:

This research examines online discussions of groups of teachers enrolled in a technology-enriched, hybrid course in mathematics education. A goal for the instructional intervention is that teachers learn to recognize children's reasoning as presented on video clips that come from a seminal collection on children reasoning in mathematics being preserved for worldwide accessibility. Setting/intervention: The intervention model involves studying videos of students across K-12 grades as they engage in cognitively challenging mathematical tasks and providing explanations of children's justifications for their solutions. We analyze online discussion within a course management system, where four groups of about 6-7 teachers engage in conversation about their mathematical problem solving. The data source include postings from a group of seven students, over a three day period, coded for Unit 8, five weeks into the strand. Full paper data will be expanded to all four groups.

Research Questions:

The questions that guide the study are: (1) How, if at all, does discussion of studying of videos contribute to knowledge of children's reasoning; and (2) What are indicators of contributing factors? Data Source: A unit over two weeks involved teacher problem solving in class, and online discussions about a video and related readings. The video involved 5 tenth graders, working in groups of two and three working on the following problem: How many different block towers can be built selecting from three colors of blocks such that the towers have at least one of each color? For the online portion, teachers were asked to describe tenth grader Romina's solution to the problem, indicate whether it is convincing and why or why not. They also were asked to compare Romina's solution strategy with those that emerged in class, and to comment on how explaining and justifying contribute to learning mathematics.

Results:

Data emerging from online discussion were coded with time stamp and for initial (I) and response (R) posts. The categories that evolved from the assignment related the videos to: problem solving (VP), value of the video (VA), examples of student reasoning (VR), and examples from the literature (VL). Teacher postings about connections of the readings to practice were also coded (RP). Studying video proved to be a strong catalyst, with 76% of the reasoning related the video and 24% related to the paper. Teacher comments reflected acknowledgement of Romina's proof as correct, clever, convincing, elegant, impressive, similar/different than that of their/other class members, to the way other members of their class solved it, similarity in notation, cleverness in notation, personally insightful, brilliantly represented, etc. The full paper will elaborate on these results, reporting on all four groups and blending quantitative analysis with qualitative evidence in the form of examples of postings made by the teachers.

Implications:

Understanding what a knowledge community looks like in practice is important for advancing our understanding of how to create and facilitate collaborative knowledge building on line and how carefully selected videos made available globally can enhance collaborative learning. Attention to student reasoning is an important aspect of mathematics teaching that can be enhanced through studying videos and thinking deeply about them.

PAPER PRESENTATION

Adaptive Teaching Strategies in German Primary Schools

Jasmin Warwas, German Institute for International Educational Research (DIPF), Germany; Andju Sara Labuhn, German Institute for International Educational Research, Germany; Silke Hertel, German Institute for Internat.Educational Research, Germany; Eckhard Klieme, Deutsches Institut fur Intern. Padagogische Forschung, Germany; Marcus Hasselhorn, DIPF, Germany

Dealing with students' heterogeneity and providing individual support to students in classroom instruction are key to teachers' work in every day school life, and are important demands of educational policy. To reach this goal, teachers can make use of several adaptive teaching strategies such as individualised worksheets and expert groups. When investigating classroom practices, teachers' beliefs play a major role. The aim of our study is to investigate what adaptive strategies teachers use, and which role both the heterogeneity of students and the teachers' beliefs play for their use. Teachers in German primary schools (N=26) reported their use of adaptive teaching strategies and their constructivist beliefs. To measure heterogeneity, we assessed the variability of grade level 3 students' (N=469) competencies in reading comprehension and mathematics in each class. Using linear regression analyses, we could not confirm a relationship between the heterogeneity of students' competencies and the self-reported use of adaptive teaching strategies. Furthermore, teachers holding a constructivist view reported a more frequent use of individualised worksheets, but they did not report to prefer expert groups. Additionally, we found significant interaction effects between the teachers' constructivist view and the heterogeneity of students' competencies regarding the self-reported use of adaptive teaching strategies. The present study reveals important implications for the development of intervention studies designed to provide individual support to students, and for implementing adaptive teaching strategies in teachers' classroom instruction.

Dealing with students' heterogeneity and providing individual support to students in classroom instruction are key to teachers' work in every day school life, and are important demands of educational policy. To this end, Corno and Snow (1986) defined adaptive teaching as "teaching that arranges environmental conditions to fit learners' individual differences" (p. 621). To reach this goal, teachers can make use of several adaptive teaching strategies such as individualised worksheets and expert groups. The former emphasise students' individual learning strategies and are quite popular in German classroom instruction. The latter is a cooperative learning method assigning students to "expert" roles, as the Jigsaw method does (Aronson et al., 1978). A large body of research shows cooperative learning methods to be effective for dealing with heterogeneity and fostering the students' achievement (e.g. Cohen, 1994; Johnson, Johnson, & Stanne, 2000). When investigating classroom practices, teachers' beliefs play a major role. Here, a direct transmission view is contrasted with a constructivist view (see Peterson, Fennema, Carpenter, & Loef, 1989; Staub & Stern, 2002). According to a direct transmission view, teachers are transmitters of knowledge. Within a constructivist framework, students are active constructors of knowledge and teachers support students' self-regulated learning strategies. Therefore, the aim of our study is to investigate what adaptive strategies teachers use, and which role both the heterogeneity of students and the teachers' beliefs play for the use of these strategies.

Hypotheses:

We hypothesize that (1) teachers use individualised worksheets as an adaptive teaching strategy in primary schools more frequently than expert groups, (2) teachers use adaptive teaching strategies particularly in classes with high heterogeneity, (3) teachers with a constructivist view use adaptive teaching strategies more frequently, and (4) teachers with a constructivist view use adaptive teaching strategies more often when they are teaching in classes with high heterogeneity.

Methods:

Teachers (N = 26) in German primary schools completed a questionnaire about their adaptive teaching strategies (e.g. 'How often do you use expert groups as an adaptive teaching strategy in your current classroom instruction?' 1 = never to 4 = in every lesson) and their beliefs (e.g. 'Students should create new ideas on their own and use individual learning strategies.' 1 = I disagree to 4 = I totally agree; three-item scale measuring a constructivist view; Cronbach's alpha = .80). Teachers were predominantly female (89%) and about a half of them had professional experience of more than ten years. Furthermore, we assessed their students' (N = 469) competencies in reading comprehension and mathematics using German standardized diagnostic instruments, such as Wuerzburg Silent Reading Test (Kuespert & Schneider, 1998) and German Mathematics Test (Hasselhorn, Marx, & Schneider, 2004). About half of these students in grade level 3 were female (52%) with a mean age of 8,8 years. To assess heterogeneity, we used the variability of students' competencies in reading comprehension and mathematics in each class. We conducted pairwise comparisons of the self-reported use of two adaptive teaching strategies: individualised worksheets and expert groups. Using stepwise multiple linear regression analyses, we tested main and interaction effects of (a) the heterogeneity of students' competencies for each class, and (b) the teachers' beliefs on the use of these strategies.

Results:

In line with our first hypothesis, a comparison of mean values revealed that teachers reported they used individualised worksheets more often than expert groups ($t(1,24) = 4.63$, $p < .05$, $R^2 F(2,22) = 7.55$, $p < .05$, $R^2 F(2,22) = 7.04$, $p < .05$, $R^2 F(3,21) > 6.95$, $p < .05$, $R^2 = .50$) or in mathematics ($F(3,21) > 10.70$, $p < .05$, $R^2 = .61$). Regarding the self-reported use of expert groups, we found a significant interaction effect between teachers' beliefs and heterogeneity of students' reading comprehension ($F(3,21) = 3.18$, $p < .05$, $R^2 = .31$), whereas the interaction between teachers' beliefs and heterogeneity of students' competencies in mathematics did not reach significance ($F(3,21) = 1.99$, $p > .05$, $R^2 = .22$). However, the significant regression weight for the interaction term ($b = 0.41$, $SE = 0.29$, $p < .05$).

Conclusion and further discussion:

In our study, the heterogeneity of students' competencies within classes was not directly related to the self-reported use of adaptive teaching strategies. However, heterogeneity in a classroom can stem from different reasons and can also be assessed in other ways, such as socioeconomic background or migration status. Also, the direction of the effects found in our explorative study should be confirmed in longitudinal studies. Furthermore, previous research shows social learning arrangements such as expert groups to be a teaching strategy dealing with students' heterogeneity as well as fostering the students' achievement. Nevertheless, this adaptive teaching strategy is quite rarely used in German primary school classroom instruction. Most likely, teachers report to use this strategy when holding a constructivist view and facing the challenge of teaching students with comparatively heterogeneous competencies. In this study, we aimed to investigate the relationship between self-reported teaching strategies and beliefs, and the heterogeneity of students' competencies. For implementing adaptive teaching strategies in teachers' work in every day school life, it is necessary to examine the teachers' current practices. Thus, the present study

reveals important implications for the development of intervention studies designed to provide individual support to students.

PAPER PRESENTATION

Effects of experience and kind of information in making achievement judgments in schools

Assessment of Competence, Cognitive Skills, Continuing professional development in Teachers; Julia Herfordt-Stopel, University of Luxembourg, Luxembourg; Sabine Krolak-Schwerdt, University of Luxembourg, Luxembourg

In a series of experiments, judgment biases and their formation in teachers' assessment of students' performance were investigated. These experiments focused on specific student attributes which, in general, should not influence the achievement assessment, e.g. socioeconomic status or migration background. Previous experiments have provided evidence that experienced teachers are less influenced by these characteristics, especially when the accountability for their decision is high (cf. Krolak-Schwerdt & Rummer, 2005). The difference between experienced and inexperienced teachers might be that they process students' characteristics in a different way. The ability of experienced teachers to ignore irrelevant student characteristics was the focus of three experiments involving different types of participants representing different career levels (experienced teachers as experts, student teachers as novices, and students as laypersons). In these experiments, a special paradigm (Mouselab; cf. Payne, Schkade, & Bettman, 1986) was used. The Mouselab paradigm makes it possible to specify which information is retrieved in what order and which information is ignored when participants search for information about students. The kind of student information which was retrieved in our experiments differed among the three groups. Experts preferred information on achievement characteristics, whereas laymen and novices favored information more connected to person evaluations in daily life. Furthermore the reproduction of the students' attributes was more correct for experienced teachers when the accountability for their judgment was high, than for laymen or novices. For the laymen, no such differences could be shown, whereas, the effects for novices were inconclusive.

Theoretical background Assessment of students is an important task for teachers. However, this assessment may be influenced by student attributes that are not achievement characteristics, such as migration background or socioeconomic background. Until now, it is not known which kind of information (grades, information about solved tasks, additional personal information, etc.) is integrated in what way into judgments. The continuum-model (Fiske & Neuberg, 1990) may help in modeling such judgments. The continuum-model distinguishes two kinds of judgment strategies.

The first strategy is the category based strategy. In this strategy, an activated category (e.g. one based on socioeconomic background or migration background) is used to judge a student. To apply the category based strategy, only low cognitive and motivational effort is needed. For this reason, the category based strategy is used for most judgments, especially when the accountability for the judgment is low. When the accountability for a judgment is high, the second strategy, the attribute based strategy, is used. In this strategy, any available information about the student is integrated into a judgment. This strategy requires much more cognitive effort but leads to less biased judgments. Beyond this, previous research has provided evidence that experienced teachers are less affected by these additional characteristics than inexperienced teachers (Krolak-Schwerdt & Rummer, 2005). This supports the assumption that certain level of expertise is needed to switch between the two strategies (Krolak-Schwerdt & Rummer, 2005), and suggests that not only the amount of information used for the judgment differs with differing levels of expertise, but also the kind of information used.

Methods

In a series of three experiments, the study tested how experts (experienced teachers), novices (student teachers), and laymen (students) search and discern information about students. For these experiments, a special paradigm, Mouselab (cf. Payne, Schkade, & Bettman, 1986) was used. By using Mouselab, it was possible to measure which kind of information (grades, sample tasks, additional information like manners or social behavior) was used to evaluate students. In Mouselab, it is not only possible to record which information is read by the participants but also the length of time and order in which information is viewed. In these experiments, half of the participants were instructed to form an impression (low accountability) while half were asked to predict the future development of a specific student (high accountability). After the instruction, participants read information about students presented in form of the Mouselab paradigm. After they were informed about a student, the participants had to give a description of that student. Furthermore, the novices took part in a special condition involving retrospective thinking aloud. Research questions and hypotheses

When the goal impression formation is activated, experts encode the student information in a category based manner. Therefore, their reproductions are biased by the activated category and they should produce more inferences. The processing data (Mouselab data) should show that participants retrieve less information under the impression formation goal. In contrast, when the goal for the experts is to give a prognosis of the students' academic development, they should integrate all information about the student in an attribute based manner. In this case, experts are expected to produce much more correct reproductions and fewer inferences. The processing data should show that experts search for more information when accountability is high.

For laymen, we expect no effects of the induced goal, because the continuum-model would predict that they are not able to switch between the two different goals. Furthermore, we believe that not only information processing itself, but also the kind of information used differs between experts and laymen. Experts should retrieve more information associated with achievement, as they are trained to do, whereas laymen should concentrate more on additional information resembling that used in daily life. For the novices, no concrete research questions were formulated. Their judgment process was only observed in an explorative manner.

Results

Concerning the recognition data, experts made more correct reproductions when they worked under the instruction to give a prediction (high accountability). Furthermore, experts made more inferences when they reported their first impression of a certain student (low accountability). For the laymen, no such differences could be shown. The novices showed no effect for the correct reproductions. However, they showed a marginally significant effect for inferences in the same direction as experts. Concerning the information which was used for judgment (Mouselab data), experts revealed a preference for information related to a students' achievement, while novices and laymen preferred information more connected to daily life (e.g. manners).

Discussion

This series of experiments gives evidence that experience is a crucial factor in making achievement judgments. For laymen and experts (experienced teachers) the expected effects on memory could be shown. Furthermore, these experiments support the assumption that information processing between experts and laymen is different and that the two groups base their judgments on different kinds of information. In summary, these results indicate the progression from laymen to experts and give important insight into the search and processing of student achievement information. On a further level, these results may help in developing training programs for student teachers. A very important point which is suggested by these experiments is that student teachers must be trained to concentrate on the important information (achievement information) and to screen out other information (migration background).

PAPER PRESENTATION

Assessing ck, pck- and pk-components of prospective teachers' diagnostic competence

Claudia von Aufschnaiter, Institute of Physics Education, Germany

Among the competences outlined to be relevant for pre- and in-service teachers, assessment and diagnosis is frequently mentioned. Teachers need to be able to identify students' conceptions and their learning outcomes and they have to monitor students' learning trajectories in order to design instruction accordingly. Even though such diagnostic competence plays an important role in teachers' professional knowledge it is yet rarely explicitly addressed in educational research. Using the distinction between content knowledge (CK), pedagogical content knowledge (PCK) and pedagogical knowledge (PK) we have set up a model to describe diagnostic competence. The model serves as a framework for both, the development of a pre-service curriculum that establishes this competence and the evaluation of prospective teachers' professional competences. Research reported focuses on first results for CK, PCK, and PK which were gathered on prospective teachers of science and mathematics. These prospective teachers demonstrate middle or high knowledge of science content and science methods but show difficulties in diagnosing students'

competences. Furthermore, no interrelation was identified between assumed moderating factors, such as attitudes or reported motivation, and the prospective teachers' PK.

Theoretical Framework and Research Aims

During the last couple of years, an increasing number of research projects have addressed teacher profession. Shulman's distinction between subject matter/content knowledge (CK), pedagogical content knowledge (PCK), and pedagogical knowledge (PK) (e.g., Shulman, 1987, see also Park & Oliver, 2008) is often used to describe teachers' professional knowledge. Even though knowledge about students' learning and methods by which this knowledge can be achieved are considered to be important aspects of professional competences, typically these are not addressed in detail in current research projects. In particular, a coherent model to describe diagnostic competence on which the design and evaluation of curricula in teacher education can be built can hardly be found in current frameworks. In order to establish and evaluate prospective teachers' diagnostic competence at university level, we have developed a framework aiming to model subject-matter related diagnostic competence (Figure 1). The framework draws on Shulman's distinction and identifies facets of (subject-matter) diagnostic competence in all three areas (CK, PCK, PK). These facets are either a prerequisite of assessment (such as content specific knowledge about the topic/subject that is to be diagnosed) or refer to the methods and results of diagnosis (such as questionnaires to assess students' prior conceptions). Furthermore, we have included competences which refer to making use of methods and results of assessment for the design of instruction. For each facet, several standards are developed which describe related competences.[Figure 1. Model for diagnostic competence]In our project, the model serves as a heuristic for two research aims. First, it informs us about the design of a curriculum which aims to establish prospective teachers' diagnostic competence. Second, the model provides the frame of reference for assessing prospective teachers' competences and the development of these competences during university training.

Procedure, Sample and Methods

The project lasts for four years (10/2008-09/2012) and comprises two cohorts of prospective teachers (at the beginning typically about 20 years old) who are monitored through their university education (which takes about 3-4 years). Cohort 1 has started in 2008, cohort 2 in 2009. All prospective teachers are included who have chosen either two sciences as subjects or a science subject and mathematics. The number of participants in each cohorts are calculated for each subject individually, numbers vary from roughly 50 (physics) to roughly 140 (biology). For educational psychology all prospective teachers are included who study for a teacher exam (N roughly 800 per cohort).In each subject and for educational psychology the prospective teachers' competences are assessed about once a year. Early in their education, the focus is on CK-components shifting slowly to increasing complex PCK-components; anchor items are included in all tests. Instruments are based on established questionnaires and tests used, for instance, in German research on teacher profession. Sample items for CK, related PCK and PK are presented in Figures 2a-c. Assessments in educational psychology also include items focusing on the assumed influencing factors (Figure 1). [Figures 2a-c. Sample items of CK-, PCK- and PK-tests aiming to assess diagnostic competence (based on Halloun et al., 1995; Riese, 2009)]In addition to summative assessments, formative assessments take place in physics and biology education. Here, the prospective teachers are videoed while working on CK- or PCK- tasks. Videos are then analyzed using surface and deep level coding procedures. These analyses have recently begun so that we cannot yet report sound results but will have those ready for the conference.

Results

During their first year of university education, our prospective teachers demonstrate similar subject matter learning difficulties than pupils do. However, the prospective teachers seem to have a good understanding of Nature of Science and science methods. Our hypothesis that a limited understanding of the content also limits the prospective teachers' ability to diagnose students' learning opportunities and difficulties seems to hold true for the majority of our population. However, some of the students (about 30%) either demonstrate high CK but low PCK or, more surprisingly, low CK and high PCK. It has to be stressed that these results are gained with relatively small sample sizes of physics students and without controlling that the level of difficulty for CK- and PCK-tests is similar. Our first analysis of participants' videos indicates that CK is important for PCK: For CK-tasks the prospective teachers rarely discuss PCK-aspects whereas for PCK-tasks a noticeable amount of time is spent on discussing the science content. The final grade in school and gender have the largest impact on prospective teachers' PK but regression analysis indicates that moderating factors for CK are different than those for PK. Those prospective teachers who hold a higher tolerance regarding bad exams show less achievement. During one year, the prospective teachers' self-evaluation of their educational skills has significantly increased even though their educational training is at the beginning.

Conclusions and Implications

The project is novel in its emphasis on trying to model and identify diagnostic competence and its development in prospective teachers. It can be expected that the model itself and results gained in the project contribute to research

on teacher profession. Even though the project is explorative in its nature, it can reveal as to whether prospective teachers will establish competences we consider to be relevant, how long such a process takes (even though it might become shorter with better learning opportunities) and what kind of learning difficulties prospective teachers encounter.

PAPER PRESENTATION

Surprising differences, hidden difficulties: findings from a teacher education pilot

Christopher Deneen, Hong Kong Institute of Education, Hong Kong; Ronnie Shroff, Hong Kong Institute of Education, Hong Kong

In the last several years, Hong Kong has undergone significant changes in quality assurance and enhancement at the tertiary level. Within this context, the Hong Kong Institute of Education, the region's largest teacher education provider has conducted an exploration of an outcome-based approach to course design, implementation and assessment within teacher education programs.

This paper reports findings from an institute-wide pilot study on OBL, implemented in 2009-2010. Pilot aims included trialing of teacher education course modifications across all undergraduate departments, analyzing and comparing students' and tutors' perceptions of the trial courses, identifying challenges within the trial process, generating evidence-based recommendations to the Institute for larger-scale implementation, and providing evidence-based findings towards to the larger teacher education community on issues of quality assurance and enhancement.

35 instructors and 672 students across 12 departments participated in the pilot. Survey, interview, focus group and related data were collected and analyzed using both quantitative analysis (item/factor scoring, ANOVA, factor analysis) and qualitative analysis (modified grounded theory). Findings include significant discrepancies between instructors' and students' perceptions of course design, assessment and implementation elements. Data analysis also revealed the significance of hidden barriers at multiple levels to change implementation. Theoretical and practical implications for institutions of teacher education contemplating or engaging in quality assurance and enhancement are discussed.

Context

In the last several years, Hong Kong has undergone significant changes in quality assurance and enhancement at the tertiary level (Kennedy, 2008; 2009). One manifestation of this has been the Hong Kong University Grants Committee's (UGC) suggestion that regional universities adopt an outcome-based learning (OBL) approach (Ewell, 2006). The Hong Kong Institute of Education is a tertiary institution serving over 7000 students. The principal focus of the Institute is teacher education. In 2007, the Institute began an exploration of OBL as a means to learner-centered quality assurance and enhancement. This paper reports on findings from the second institute-wide pilot study (Pilot II) on OBL, implemented in 2009-2010.

Aims

Five principal aims of Pilot II:

1. Within an OBL paradigm, enact a trial of teacher education course improvements across all undergraduate departments
2. Analyze and compare students' and instructors' perceptions of trial courses
3. Identify challenges within the trial process
4. Generate evidence-based recommendations to the Institute for larger scale implementation
5. Generate evidence-based findings that may inform the larger teacher education community on issues of quality assurance and enhancement

Methodology

Sample

35 instructors and 672 students participated across 12 departments.

Data collection

Two survey instruments were developed, an Instructor Survey Instrument and a Student Survey Instrument. Instruments were constructed from the same item matrix, which allowed for comparisons in response between instructors and students. Both instruments used a positively-loaded six-point scale (Lam & Klockars, 1982), and open-response items. Qualitative data was collected through instructor professional development sessions, instructor group sharing sessions, and student focus groups. Ethnographic interviewing techniques (Spradley, 1979) and Morgan's (1997) focus group protocols were utilized.

Data Analysis

Data was subjected to qualitative and quantitative analysis. Confirmatory Factor Analysis (CFA) was used on student survey data. CFA was not used with instructor survey data due to sample size restrictions. Analysis of mean, mode, standard deviation, was applied to both instructor and student survey data as well as ANOVA. Qualitative data was coded using a modified Grounded Theory technique (Strauss & Corbin, 1990).

Findings

Factor Analysis

CFA demonstrated the existence of five factors. Inter-correlation values and fit statistics indicated that respondents saw these factors as separate but related components of the pilot course:

1. Course Intended Learning Outcomes (CILOs)
2. Planning, design and alignment
3. Learning and teaching activities
4. Course assessment
5. Feasibility/Comparison

Findings from the fifth factor have been integrated into the discussion of the four course planning and implementation factors.

CILOs

Students evaluated this factor quite highly; CILO factor mean on the student survey was 4.31. Mean factor score on the instructor survey was 4.42, indicating strong parity between students' and instructors' evaluation of CILOs. This factor represents the area in which there was greatest course change as seen through analysis of professional development and sharing session data. Student-generated data reinforced the above findings; students perceived CILO-specific differences from other courses they had taken. Data indicated students placed a high value on outcomes that that were practice-oriented.

Planning, design and alignment

This factor received positive ratings from both students and instructors. However, there were concerns as to whether this factor was conceptualized similarly by students and instructors. CFA analysis of the student survey revealed a strong (.97) inter-correlation between this factor and the factor, learning and teaching activities of the course." Fit statistics revealed that despite this inter-correlation, a model with separate factors was more viable. One hypothesis to explain this finding is that students viewed course planning and design differently than instructors. Qualitative and quantitative data from instructors support the hypothesis.

Learning and teaching activities

This factor received highest overall evaluation by students. Factor mean was 4.33. Qualitative data supports this positive impression. However, student ratings negatively correlate to year in degree program. This finding held across the first four factors but it was most pronounced within learning and teaching. One hypothesis is that students' evaluative criteria become more refined as they progress in the degree program. This interpretation is supported by related research into variance in SET scores by student characteristic (Sailor, Worthen, & Shin, 1997).

Course assessment

Students evaluated this factor category lowest out of all four impact categories. Factor mean was 4.08. This factor category yielded the greatest variance between student and instructor evaluation. Assessment factor mean on the tutor survey was 4.82. Larger-scale analysis of data suggests that classroom assessment was the area of least change within Pilot II. Findings suggest this lack of change was due to multiple factors including administrative barriers and participating instructors' response to change initiatives.

The subset of instructors and students who did make/experience changes in course assessments experienced significantly different results. Open-ended survey responses as well as interview data yielded strong positive response from both groups.

Theoretical and educational significance

Pilot II had strong interaction with unanticipated context issues, such as institutional policy and procedures. Impact was especially pronounced in assessment findings. Attention within the paper is given to understanding these interactions and how findings could be of significance to institutions engaged in quality assurance and enhancement.

Understanding the significant aggregate gap between instructor and student evaluations of classroom assessment has theoretical significance in relation to an emerging field of inquiry: stakeholder conceptions of assessment (Brown, 2006; 2009; 2010). The subset of courses where there were changes to assessment produced significantly different results. The paper discusses theoretical implications and practical possibilities for fostering change in course assessment and addressing challenges to implementation and adoption.

Findings related to planning and teaching are of special significance to teacher education and the preparation of student teachers in the practice of course planning and teaching. Designing transparency into courses is discussed, both as a design element within teacher education courses and as a skill to be taught to student teachers.

The paper also discusses findings on teaching and learning in relation to strategizing student engagement according to progress within degree programs. Implications for teacher education program design are discussed, in terms of outcome development, course leveling, and course mapping/sequencing.

PAPER PRESENTATION

Personalisation in (Initial) Teacher Education

Christian Kraler, Teacher Education and School Research, Austria

Globalisation influences teacher education in Europe especially since the introduction of the Bologna process. This forces governments and universities to reform their teacher education programs. Competence-oriented programs imply the chance to plan initial teacher education outcome oriented and at the same time to increase the process specific flexibility for the course of education of individual students. Thus the idea is to develop a flexible curriculum matrix for a teacher education program with regard to the objective profession-specific course of education defined by competencies and the individual, personal course of education concerning choices, prevailing conditions and other biographical aspects.

In this talk the main findings of a study based on interviews with graduates of a competence oriented teacher education curriculum, a curriculum analysis and quantitative context data will be presented. The research question of the study is: "What are student based developmental tasks during a competence oriented teacher education program?" One result is that we do have two different only partially overlapping cultures of initial teacher education. Based on the concepts of developmental tasks and personalised learning we try to integrate the different approaches into the design of a flexible curricular matrix for initial teacher education with regard to the findings of the study and the existing literature.

One of the effects of the technology-based globalisation of markets is the current status of the individual. The logic behind this seems to be that everything is potentially available at any time for anybody. The responsibility is delegated to the individual. On the other hand, we find that institutions or governments control processes of all kinds increasingly by prescribing detailed structural and content-specific standards for the individual's actions. The same, at least in the German speaking countries, goes for educational systems and especially for teacher education. The modularisation of teacher education programs at universities initiated by the Bologna process (following the logic of global or continental markets) has led to more choice and flexibility for students. Yet on the curriculum level we now find a higher fragmentation of contents. This probably makes the essential profession-specific task of integrating the different elements of initial teacher education for both, the individual teacher student and teacher educators, more challenging than before.

On the other hand, the consequences of this global thinking can be a big chance for teacher education and in particular for the very specific, traditionally government controlled and inflexible teacher education systems in Austria and Germany. The changing framework forces governments and universities to reform their teacher education programs. Thus the internationalisation of teacher education and the necessary governmental reaction to the big international student assessments has led to the implementation of competence-oriented teacher education curricula. As the increasing research literature on this topic since the turn of the century shows, the definition of profession-specific competencies at least improves transparency regarding the efficacy of the teacher education system. Curricular competencies and Bologna modules would offer a profession-specific raster for the individual

teacher education student. Carefully implemented, such curricula for teacher education imply the chance to plan initial teacher education in view of the outcome (what are minimum requirements for beginning teachers?) and at the same time increase the process-specific flexibility for the individual course of education. Students have more choices with regard to their individual strengths and weaknesses.

The study presented moves within this context. The underlying question is this: How can a competence-oriented university-based teacher education program be developed further into a profession-specific, personalised course of education?

The theoretical framework of our research into teacher education at the University of Innsbruck is threefold. The starting point is Kant's pedagogical question: How can I cultivate freedom under constraint? Based on this question we adapt Havighurst's concept of developmental tasks (cf. Trautmann 2004), the concept of the course of education (Meyer M. 2007) and put it in the context of personalised learning (Des 2006). The idea is that teachers need to experience successful ways of teaching for our changing society during their own professional education at university that implies personalised learning and an individual course of education. Taking into account institutional limits and reasonable common standards for beginning teachers a matrix of curricular modules and profession-specific competencies might lead to a flexible set of specific developmental tasks for students. Personalisation would imply that not all these tasks need to be taken on by every student and that the order must remain flexible.

The University of Innsbruck has implemented a competence-oriented, portfolio-supported teacher education program in 2000 (Kraler 2008). It is based on curricular developmental tasks for every academic year (e.g. 1st year: trial identification, self-assessment, shift in perspective from pupil to teacher, introduction & fit). After ten years of experience we get positive feedback from schools and school authorities. But at the same time an ongoing evaluation study has shown that the students view their education as too inflexible and rigid. The next logical step for program development was to systematise the feedback and the student experiences (Kraler 2009). So the central research question of the study is: What are student-based developmental tasks during a competence-oriented teacher education program? The objective, ultimately, is to develop a flexible curriculum matrix for our teacher education program with regard to the objective profession-specific course of education defined by competencies and the individual course of education concerning choices, prevailing conditions, etc. In the context of our personalised concept we used a qualitative approach and held 25 profession-specific biographical interviews, on a voluntary basis, with graduates of our teacher education program. The interviews covered questions from the origin of the idea of becoming a teacher, the school career, the experiences at university, familial and private influences, up to next steps after graduation. The average duration of the interviews was between 1h20min and 2 hours. In keeping with our gender distribution, there were 7 male and 18 female interviewees. In addition to the interviews we could analyse the portfolios of the interviewees and, as a quantitative element, take into account all the students' grades. The data analysis was done computer-supported (MaxQDA), using a combination of grounded theory, metaphor analysis and hierarchical content analysis. The grades contextual biographical data were analyzed with SPSS. We also analysed the curriculum (18 different subjects), focusing on the description of competencies.

The main findings are:

Prescribed program/curriculum-based developmental tasks: - Trial identification - Understanding fundamental ideas of the relevant subjects - Teaching internships to test out acquired competencies - Readjustment & amendment (based on the experiences from the internship) - Diploma certification Student-based developmental tasks (interviews, portfolios): - Role allocation: growing into the role of the student - Relations: disengaging from the parental home, relationship/new friendships/old friendships sustained, students studying together - Dealing with frustration concerning course organisation and specific contents - Subject-specific socialisation (faculty culture) - Change of perspectives through periods spent abroad (especially when studying languages) - Earning money (subject-related, e.g. tutoring, or non-subject-related, often also just to get a change) The last part of the presentation will deal with our first approaches to designing a flexible curricular matrix for initial teacher education based on the findings of the study mentioned.

PAPER PRESENTATION

Wisdom-related competence in teacher education - an adapted model of psychological wisdom research

Robin Stark, Saarland University, Germany; Miriam Hoffmann, Saarland University, Germany

Wisdom-related competence supports effective action in complex social situations as for example in an educational setting. Our concept of wisdom-related knowledge postulates 14 knowledge and attitude categories which constitute wisdom-related competence. We distinguish wisdom-relevant and wisdom-specific knowledge and attitude dimensions. In order to investigate the level of wisdom-related competence in teacher candidates, we generated

complex scenarios situated in an educational context. 49 teacher candidates processed these scenarios in two different learning conditions: problem-based learning (n=24) and analysis of erroneous examples (n=25), plus a control group of n=9. In the pretest, we assessed "wisdom" through the three-dimensional Wisdom Scale (3d-WS) and the Self-Assessed Wisdom Scale (SAWS) and tolerance of complexity through the Tolerance of Complexity Scale. We performed a content analysis on the written answers of pre- and posttests using a specific coding manual and the software MaxQDA. Means were higher in the post- than in the pretest but still at only 35% (problem-based condition) resp. 36% (erroneous example condition) of the theoretical maximum. There were no significant differences between experimental conditions, but both experimental conditions outperformed the control group. A significant predicting factor for posttest achievement proved to be the prior level of wisdom-related competence as assessed in the pretest. Posttest total scores' correlations to the three additionally implemented scales missed statistical significance, whereas posttest scores of some wisdom-related dimensions correlated at least partially to the 3d-WS, SAWS and the Tolerance of Complexity Scale.

Aims: Based on the Berlin Wisdom Paradigm (e.g. Staudinger & Baltes, 1996a) and the Balance Theory of Wisdom (Sternberg, 2001), our model of wisdom-related competence distinguishes 14 wisdom-relevant and wisdom-specific knowledge and attitude dimensions (Hoffmann & Stark, 2009), the first being necessary, but not sufficient prerequisites for the development of wisdom whereas the latter describe aspects characteristic for people whose actions could be considered to be "wise".

We tried to reveal the level of wisdom-related competence in teacher students as we consider everyday school life as a highly complex and very dynamic working environment where dealing with wisdom can provide valuable "orientation knowledge" (Staudinger & Baltes, 1996a) in order to facilitate complex problem-solving.

We investigated whether wisdom-related competence can be fostered by a short scenario-based learning environment with either a problem-based learning approach or by processing erroneous examples.

In order to validate our wisdom model respectively our coding system, we compared the results of our assessment method to two existing wisdom scales (3dWS, Ardel, 2003; and SAWS, Webster, 2003) and a scale for assessment of tolerance of complexity (Radant & Dalbert, 2006).

Methodology

Sample

Participants were teacher students (n=63, 40 female, 23 male), between 19 and 36 years old (M=22.13; SD=3.80), who during their studies underwent a practical training of five weeks. They all participated in the pre- and posttest; the two experimental groups worked with a learning environment in the problem-based learning (n=24) or the erroneous example (n=25) condition.

Scenarios

We developed four scenarios dealing with problematic situations in everyday school life. Two of them were used in the pre- and/or post tests, two only in the experimental conditions.

Problem-based learning vs. Learning from erroneous examples

In the problem-based learning condition, participants had to process a scenario and compare their own answer to a sample solution given by a fictitious psychologist.

In the erroneous example condition, the erroneous example consisted of a given answer by a fictitious laymen. This erroneous example had to be compared to the sample solution.

Coding manual

The coding manual comprises 14 categories (Hoffmann & Stark, 2009). Answers are coded according to their congruence with an ideal answer on a 7-point-scale.

Wisdom Scales

3d-WS: This scale by Ardel (2003) consists of 39 items belonging to either the cognitive, affective or reflective subscale, each item is rated on 4- resp. 5-point Likert scales.

SAWS: The SAWS (Webster, 2003) comprises 40 items belonging to one of the five subscales "Experience", "Emotional Regulation", "Reminiscence/Reflection", "Humour" and "Openness" with a 6-point Likert scale.

Tolerance of Complexity Scale: This scale (Radant & Dalbert, 2006) assesses tolerance of complexity in three subscales ("Challenge", "Pressure" and "Necessity") of 20 items each on a 6-point Likert scale.

Findings

Concerning pretest performance and tolerance of complexity, learners of the three groups did not differ significantly. Total scenario scores (theor. max.: 98 points) in the posttest ranged from 21 to 56 points in the erroneous example condition ($M=35.72$; $SD=9.14$; 36% of theor. max.), from 14 to 49 points in the problem-based learning condition ($M=34.58$; $SD=10.81$; 35% of theor. max.), and from 17 to 35 points in the control group ($M=26.67$; $SD=5.96$; 27% of theor. max.). There were no significant differences between the two experimental groups. Both experimental groups clearly outperformed the control group. For all groups, pretest scores were strong predictors for posttest performance. There was no interaction between pretest scores and experimental condition. Correlations between posttest results and the Tolerance of Complexity Scale, 3d-WS and SAWS missed statistical relevance. Tolerance of Complexity correlated with "domain-specific background knowledge" ($r=.29$, $pr=.29$, $pr=.27$, $pr=.29$, $pr=.27$, $pr=.34$, $pr=.27$, $pr=.30$, p

Theoretical and educational relevance

On an abstract level, results indicate an existing deficit in teacher candidates concerning wisdom-related competence. More concretely, our results show that aspects of wisdom-related competence can be fostered effectively and economically by a scenario-based learning environment. Similar results can be achieved by problem-based learning and learning by erroneous examples. However, they also show that both approaches are not effective enough to develop wisdom-related competence. We suppose that in order to come closer to this goal, both approaches have to be implemented for a longer period. They should be combined with additional instructional support, e.g. innovative feedback methods. Based on findings by Staudinger & Baltes (1996b), we propose that these methods could be realized by implementing forms of cooperative learning (e. g., reciprocal teaching; Palincsar & Brown, 1984). The correlations between aspects of wisdom-related competence assessed by our coding procedure and the two wisdom scales can be interpreted in terms of first indicators for convergent validity.

PAPER PRESENTATION

Model Competence in Biology Education – Evaluation of a Theoretical Structure Using Open-Ended Tasks

Juliane Gruenkorn, Freie Universitaet Berlin, Germany; Dirk Krueger, Freie Universitaet Berlin, Germany

Various studies have shown that most of the students' conceptions of models differ from scientific conceptions (e.g. Grosslight et al. 1991). Students reflect little on their thinking in and handling of models and are not aware of the role models play in an epistemological process (e.g. Grosslight et al. 1991; Trier & Upmeyer zu Belzen 2009).

If teachers know about students' conceptions, they can provide adequate support for learning about models. In the long term, diagnostic instruments have to be designed. Upmeyer zu Belzen and Krueger (2010) have developed a model of model competence that could serve as a theoretical basis for such instruments. However, first this theoretical structure needs to be evaluated empirically.

The aims of this research project are to operationalize and evaluate this theoretical structure. 25 open-ended tasks were designed and tested for understandability and consistency with the theoretical structure on a sample of 1059 students. The data were analyzed by qualitative content analysis (Mayring 2003). The analysis of the student answers showed few difficulties to understand the tasks. Difficulties mainly occurred with the instruction and certain biological topics e.g. genetics. The majority of the student answers are consistent with the theoretical structure. But additional facets such as the uniqueness of models need to be considered. Results of the study will be presented at the EARLI 2011.

PAPER PRESENTATION

Conditions and Consequences of Assessment Practices and Judgment Accuracy

Anika Buergermeister, DIPF, Germany; Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

Assessment processes are prominent in instruction and teachers devote a substantial amount of time to measure, evaluate and report on students' performance. For that reason, the present contribution addresses two main issues concerning classroom assessment, namely assessment practices and accuracy of assessment, as correct and precise judgements are demanded, in order to adequately plan and enhance instruction. The focus is on effects of different assessment practices as well as on conditions for assessment accuracy. More precisely, the study (N = 46 teachers, N = 950 students; 9th grade secondary school) investigates three research questions: Do different classroom assessment practices (grade-centred, verbal, participatory) in mathematics instruction impact students' motivation and performance (1)? Findings reveal that a grade-centred assessment practice in mathematics instruction, in which students are not actively involved in the assessment process, is negatively correlated with students' motivation as well as students' test performance. To which extent do teacher variables (2) and classroom assessment practices (3) have an effect on teachers' judging accuracy? Results prove that a higher knowledge concerning the aspect of assessment, more experience in teaching the students as well as a participatory assessment practice cause a higher, while a grade-centred assessment approach leads to a lower judging accuracy. In sum, findings suggest, that classroom assessment is a crucial element of instruction and may be relevant on the one hand for students' learning process and on the other hand for teachers' ability to evaluate their students' achievement and as a result appropriately plan instructional processes.

Background

Teachers spend a substantial amount of time carrying out activities in order to assess students' performance and achievement in instruction (Stiggins & Conklin, 1992). Assessment, which Hattie and Timperley (2007) define as activities that provide teachers and/or students with feedback information [...] can be seen as an essential instructional tool by providing accurate and important information on student learning and its progress. This information from ongoing classroom assessment is essential for instructional decisions and classroom management (Begeny et al., 2008). Additionally, researches have proved an impact of assessment practices themselves on students (e.g. Brookhart, 1997). Bol et al. (1998) found that the use of various assessment strategies as well as alternative forms of assessment (e.g. portfolios) have a positive effect on students' motivation and performance. In this context, the importance of actively involving students in the assessment process is emphasized in several studies (Stiggins & Chappuis, 2005). It is assumed, that giving students an active role in monitoring and reflecting their own level of achievement as well as their strengths and weaknesses may positively influence their learning process (e.g. van Gennip, 2010).

Besides the effect of assessment practices, the teachers' ability to precisely assess students' achievement is a relevant issue in the context of classroom assessment. Only by accurately judging students' performance, teachers are able to adequately adapt their instructional processes and methods to students' needs and requirements. However, to what extent teachers are able to give exact judgments can vary considerably (Hoge & Coladarci, 1989; Perry & Meisels, 1996) and may depend for example on students' characteristics or teacher and classroom variables (Bates & Nettelbeck, 2001; Hurwitz; Demaray & Elliott). In this context, Martínez, Stecher and Borko (2009) claim that different assessment methods of students' performance lead to different accuracy in judging this performance.

Aim of the study

The present study aims at investigating the two outlined aspects of classroom assessment, namely consequences of classroom assessment practices and conditions of judgment accuracy in mathematics instruction. It is intended to explore the impact of classroom assessment practices (grade-centred, verbal, participatory) on students' motivation, effort and performance (1). Moreover the study focuses on teachers' judgment accuracy in assessment processes. Concerning this aspect we aim at investigating conditions of teachers' judgment accuracy. More precisely it will be

examined, in what way teacher variables (2) and classroom assessment practices (3) may influence the assessment accuracy of students' mathematical competence.

Method

The sample consists of 46 mathematics teachers and their 950 students. The students, attending the ninth grade of the middle school, worked on a mathematics test which contained tasks referring to the area Theorem of Pythagoras and Linear Equations, covering either technical (knowing and using formulas and definitions, calculating) or modelling competence (translating a real-world problem into a mathematical problem).

In addition, we measured students' test motivation and effort by implementing a questionnaire. As we consider reference norms to be an important aspect of assessment processes, students were also asked to report on their teachers' reference norms used in assessment processes.

The teachers completed a questionnaire focusing on the one hand on the use of classroom assessment practices. Here we distinguished a grade-centred assessment form which mainly contains an explicit assessment, implemented by the teacher, which is essentially realized by giving grades, from a participatory assessment practice which includes, that students are actively involved in the assessment procedure (self- & peer-assessment, portfolio). Furthermore we measured how often teachers use a verbal kind of assessment practice, which mainly involves a verbal feedback for the students and the oral explanation of common mistakes or misunderstandings.

On the other hand the questionnaire measured teachers' ability to accurately judge students mathematical competences. Teachers were asked to estimate each student's technical and modelling competence.

Furthermore, we asked for the teachers' demographic characteristics such as gender, age, experience in teaching this class in mathematics and moreover measured their self-reported knowledge concerning the issue of assessment. As our data is characterized by a multi-level-structure, we conducted multilevel – multiple - regression - analysis.

Results

Analysing the first research question, results reveal, that a grade-centred assessment approach is negatively related to students' motivation ($b = -.10^*$) as well as to students' test performance in technical ($b = -.11^*$) and modelling tasks ($b = -.16^{**}$). Beyond, if students perceive an individual reference norm in their teachers' assessment activities it indicates a positive link to their motivation ($b = .13^{**}$), effort ($b = .10^{**}$) and performance ($b = .13^{***}$).

Concerning the second research question, we found, that teachers' knowledge about assessment positively moderates the association between students' performance in technical items and teachers' judgment ($b = .07^*$). Furthermore it is proved, that the experience in teaching this particular class in mathematics positively moderates the accuracy of teachers' prediction of students' performance (technical competence: $b = .13^{**}$, modelling competence: $b = .11^{**}$). Findings referring to our third question reveal that a grade-centred approach negatively moderates the accuracy of teachers' assessment (technical competence: $b = -.12^{**}$, modelling competence: $b = -.08^*$). In contrast, a participatory assessment form seems to positively influence the accuracy of judging students competences (technical competence: $b = .08^*$, modelling competence: $b = .08^*$).

Discussion

Findings support existing assumptions (Stiggins & Chappuis, 2005; Rodriguez, 2004) that assessment strategies may affect students' motivational and cognitive characteristics. As expected, taking individual improvements and differences in assessment processes into account, positively influences students' motivation. The negative effect of a grade-centred approach might be due to the fact, that grades are perceived as controlling and therefore negatively affect students' intrinsic motivation and performance (Butler, 1988).

Concerning the aspect of judgment accuracy in assessment processes it seems to be important that teachers have knowledge about assessment and experience in teaching the students.

It is to be concluded, that classroom assessment is not only important for measuring students' skills and achievement, but also needs to be seen as an essential tool, which may influence students' learning process and teachers' judging accuracy.

PAPER PRESENTATION

Modelling item position effects and students' individual persistence in standardized assessments

In standardized educational assessments, performance of students can decrease with long tests due to fatigue or declining motivation, i.e. the position of an item within a test has an effect on item difficulty. The present paper aims to analyze these item position effects within the PISA 2006 science assessment to obtain knowledge about the general size of these effects (how much does performance decrease in the course of the assessment) and about individual differences in item position effects, i.e. the students' persistence during the assessment. Furthermore, the correlation between the students' performance level and their persistence is analyzed. The analyses make use of the published science assessment data from the PISA 2006 study consisting of data from $N = 397.920$ students from 57 countries. Responses to 103 science test items were used in the analysis. All effects of interest were analyzed separately for each country, allowing to compare the effects across countries. A small effect of item position on item difficulties was found consistently across all countries, regardless of their national performance level. The individual differences in persistence were relatively small in all countries, but more pronounced in countries with low performance levels than in high performing countries. Students' performance level is practically uncorrelated with persistence in high performing countries, while it is negatively correlated within low performing countries.

In standardized educational assessments, performance of students can decrease with long tests due to fatigue or declining motivation, i.e. the position of an item within a test has an effect on item difficulty. An examination of these effects is interesting for several different reasons: For example, if item position effects are known, the maximum test length that can be administered to students without overly impairing the assessed performance can be determined. More importantly, if item difficulties are used to describe test scores by construct maps (e.g., Wilson, 2005), effects of item positions should be separated from differences in item difficulties due to item content. In addition to the main effects of item positions (e.g. a general increase in item difficulty), students may also differ individually in item position effects. The performance of some students may remain stable even across long tests, while the performance of others may decrease faster. To analyze individual differences in item position effects is appealing as these individual differences reflect the individual tendency to change (and most probably decrease) performance in the course of an assessment. This individual tendency can be interpreted as a student characteristic of its own right, providing additional diagnostic information over and above the individual performance level. Within this paper, we will refer to the individual effect of item positions as persistence: low individual persistence means decreasing performance, high persistence means stable or even increasing performance throughout the assessment.

In tests with fixed item orders, however, the difficulty of the actual item content and effects of the item position within the test cannot be separated since every item is always presented at the same position, e.g. at the beginning or the end of the test. Therefore, neither effects of item position nor individual differences in persistence can be estimated. Only if item position and item content are not confounded, the general examination of item position effects as well as of respective individual differences between students is possible. This is the case in data from large scale studies that implement balanced booklet designs, as in the OECD Programme for International Student Assessment (PISA) or the Trends in International Mathematics and Science Study (TIMSS).

Aim of the Study

The present study examines general item position effects and individual differences in persistence using public data from the PISA 2006 science assessment. The first aim is to assess the size of a general item position effect and the consistency of this effect across countries with different national performance levels. Second, variances in students' persistence are estimated and compared between countries. Finally, the correlation between students' performance level and persistence is estimated for different countries. A positive correlation implies that the performance of low performing students decreases faster in the course of the assessment, whereas a negative correlation indicates that higher performing students tend to decrease their performance.

Method

The analyses make use of the published science assessment data from the PISA 2006 study (OECD, 2010) consisting of data from $N = 397.920$ students from 57 countries. Responses to 103 science test items were used in the analysis. In PISA 2006, items were presented in a completely balanced booklet design with each booklet consisting of four blocks of items. Each item was presented equally often at all of the four possible block positions within the booklet, i.e. item position and item content were varied independently. The item responses were analyzed using a logistic multilevel model treating responses as level one variables nested within students. With only fixed effects for item difficulties, this model is equivalent to the Rasch model which was originally used to analyze the PISA data. In addition to the effects of item content (i.e., the item difficulties) the model was extended to include the main effect of the item position within the booklet and an associated random effect to capture individual differences in persistence. The

model allows an estimation of (1) the general effect of the item position, (2) the amount of variance in persistence, and (3) the correlation between the performance level and the persistence. The three effects were estimated separately for each country.

Results

A small effect of item position on item difficulties was found consistently across all countries, regardless of their national performance level. For example, the percentage of correct responses decreases from 35% to 29% from booklet position one to four in Brazil and from 59% to 55% in Finland. The individual differences in persistence were relatively small in all countries, but more pronounced in countries with low performance levels (e.g. Brazil and Turkey) than in high performing countries (e.g. Finland and Korea). The most striking difference between countries was found with respect to the correlation between students' performance levels and persistence. In high performing countries, item position effects were practically uncorrelated with the performance level (e.g. $r = ?0.032$ for Finland or $r = ?0.019$ for Korea). In low performing countries, however, the performance level is negatively correlated with the individual item position effect (e.g., $r = ?0.367$ for Brazil, $r = ?0.388$ for Tunisia or $r = ?0.399$ for Thailand. This means that particularly the higher performing students in these countries tend to decrease their performance in the course of the assessment.

Implications

The general effect of item position confirms the already known negative effect of test length on performance. However, the effects are relatively small and do not indicate that the two-hour testing session for PISA 2006 was too long. The negative correlations between performance level and persistence in the low performing countries indicate that one (although small) contribution to these countries' test results may be that higher performing students aren't able to keep up their performance level across the whole assessment. Finally, the analyses demonstrate that item position effects as well as individual differences in these effects can conveniently be analyzed in a standard multilevel framework.

PAPER PRESENTATION

Students' Test Motivation in PISA

Therese Nerheim Hopfenbeck, University of Oslo, Faculty of Education, Norway; Marit Kjaernsli, ILS, University of Oslo, Norway

Abstract

There is an ongoing discussion as to whether large scale assessment studies such as the Programme for International Student Assessment (PISA) have biased test scores due to students' lack of test motivation (Baumert and Demmrich 2001). One of the main concerns is that low-stake assessments, having little consequence for students, teachers or schools underestimate students' ability (Holliday and Holliday 2003; Sjöberg 2007). If lack of test motivation is not measured and controlled for, it might be a threat to the validity of the interpretation and use of test scores (Eklöf 2010). Despite these concerns, there is a lack of empirical research regarding students' test motivation in large scale assessment studies. This paper will present two studies conducted in Norway which investigated students' test motivation while participating in the PISA test. Questionnaire data ($N = 4600$ students) will be presented together with interviews of Norwegian students who participated in the PISA study in 2006 ($N = 22$) and 2009 ($N = 11$). The preliminary findings show that students report to have been fairly motivated despite the low-stake testing of PISA.

Aims

This paper will present two studies conducted in Norway which investigated students' test motivation while participating in the PISA test. Questionnaire data ($N = 4600$ students) will be presented together with interviews of Norwegian students who participated in the PISA study in 2006 ($N = 22$) and 2009 ($N = 11$).

After the PISA 2003 cycle, results showed that overall, students answered that they would have put more effort in the test if it would have influenced their school marks, but it was also found that the expenditure of reported effort by students were fairly stable across countries (Butler and Adams 2007).

In Germany a study was conducted with the aim to investigate whether teachers coaching of PISA items would influence the achievement scores in mathematics and reading. Overall, the researchers did not consider pretesting and coaching a threat to the validity of the PISA study (Brunner, Artelt et al. 2007). In the United States another study

investigated monetary incentives when using released TIMSS mathematic items on a test. The experiment did not show any improvement of the performance, and the speculations about the lack of test motivation in American students as a cause of the poor results on the TIMSS study were rejected (O'Neil, Abedi et al. 2005).

The two studies presented in this paper draw upon this previous research, in addition to research conducted in Sweden (Eklöf 2006; Eklöf 2007) and the United States where researchers have developed and validated a questionnaire measuring students' test motivation; the Student Opinion Scale and the Motivational Scale (Wolf and Smith 1995; Sundre and Moore 2002; Sundre 2007).

Methods

In order to further explore students' test motivation on the PISA test, seven items were developed and used as national options in the student questionnaire booklet in the spring of 2009. A sample of 4600 students reported their test motivation on this instrument. The items build upon the work described by Eklöf and her work on TIMSS students in 2003. In addition, we have adapted some of the items from the Student Opinion Scale and the Test Motivation Scale to measure Effort and Importance. Following the research of Sunder and More (2007) we conducted reliability tests and based upon these analyses, we decided upon a four-item motivation construct for use in the PISA 2009 test. Eleven students were interviewed to investigate item understanding and to learn more about students' responses. The interviews were semi-structured, and based on an interview guide used in a previous study of how students experienced the PISA 2006 test (Hopfenbeck 2009). Students' were asked how the school had been preparing them for the test, how they experienced the test and whether they believed they were able to do their best.

Findings

The preliminary findings show that students report to have been fairly motivated despite the low-stake testing of PISA. Complete results will be published in December 2010 together with the PISA 2009 findings.

Significance

This paper is a contribution to the ongoing discussion as to whether large scale assessment studies such as the Programme for International Student Assessment (PISA) have biased test scores due to students' lack of test motivation (Baumert and Demmrich 2001). One of the main concerns is that low-stake assessments, having little consequence for students, teachers or schools underestimate students' ability (Holliday and Holliday 2003; Sjöberg 2007). If lack of test motivation is not measured and controlled for, it might be a threat to the validity of the interpretation and use of test scores (Eklöf 2010). Despite these concerns, there is a lack of empirical research regarding students' test motivation in large scale assessment studies.

PAPER PRESENTATION

Two Deaf students participating in a mainstream mathematics class

Ines Borges, Universidade Nova de Lisboa, Faculdade de Ciencias e Tecnologia, Portugal; Margarida Cesar, Universidade de Lisboa, Instituto de Educacao, Portugal

National and international policy education documents stress the need to provide an inclusive education (ME, 2008; UNESCO, 1994), but students categorised as presenting special educational needs still face many barriers in their access to achievement (Cesar & Ainscow, 2006). In Portugal, Deaf students experience different forms of school and social exclusion, like higher underachievement in many subjects such as mathematics (Borges, 2009) and lower percentages concerning the attendance of the university (Almeida, 2009).

We focus on the participation in mainstream mathematics classrooms of two profound and severe Deaf students. They were pre-lingual, oralist and attended the 12th grade. Assuming an interpretive approach (Denzin, 2002), we developed two intrinsic long-term case studies (Stake, 1995), one for each Deaf student. We consider these participants: the two Deaf students, their classmates, mathematics and special education teachers. The data collecting instruments were the observation (recorded in the researcher's diary and audio-taped), interviews, informal conversations, students' protocols and documents. The data treatment was based in a narrative content analysis (Clandinin & Connelly, 1998) from which inductive categories emerged (Cesar, 2009).

Through the analysis of some episodes and empirical evidence we address adaptations made by their teacher that helped Deaf students to give a meaning to mathematics (Bakhtin, 1929/1981), learn it and become legitimate participants (Cesar, 2009). We also acknowledge the five interactive patters we identified in these mathematics classes (Borges, 2009) and how they facilitated students' transitions (Zittoun, 2006), namely from the mainstream culture and knowledge to the Deaf culture and these students' daily knowledge.

Schools are multicultural settings (Abreu & Elbers, 2005; Cesar, 2009). National and international policy education documents suggest a more inclusive schooling (ME, 2008; UNESCO, 1994). But opening the mainstream classrooms to students categorised as presenting special educational needs (SEN) is not enough. Classroom practices must befit students' needs, characteristics and interests. In Portugal, this need is more urgent in mathematics as this subject is often associated with underachievement, rejection, low positive academic self-esteem and poor engagement in classroom activities (Cesar, 2009; Cesar & Santos, 2006). Moreover, there is a lack of studies regarding advanced mathematics learning and Deaf students (Borges, 2009). Thus, teachers claim they have no data illuminating how to improve Deaf students' learning processes. As stated by Sfard (2001, 2008), learning and thinking is communicating. The barriers Deaf students face when communicating with the mainstream hearing community shape their school and social paths (Freire & Cesar, 2003; Sim-Sim, 2005). At Lisbon University Deaf students present the lowest percentage of attendance among SEN cases (Almeida, 2009). In order to include Deaf students in mainstream classes teachers have to facilitate the establishment of a shared communication system, allowing every student to participate in the classroom interactions and activities (Borges, 2009).

The barriers in the communication and in their access to the school mathematical tools experienced by Deaf students included in mainstream classes are the problem that originated this study. We focus on three research questions: (1) What adaptations in classroom practices are performed by this teacher in this 12th grade class that includes Deaf and non-impaired teenagers?; (2) What adaptations are performed by the non-impaired students in their communication while working and interacting with these two Deaf students?; and (3) How do these two Deaf students construct their access to the cultural tools of school mathematics?

We assumed an interpretative approach (Denzin, 2002) and an intrinsic long-term case study design (Stake, 1995). These Deaf students were oralist, pre-lingual and profound and/or severe and they attended the same 12th grade mainstream class. They were considered academic successful cases as each one of them had only doubled one school year. We chose these characteristics intentionally as disclosing successful cases promote the development of a more inclusive education (Armstrong, Armstrong, & Barton, 2000; Cesar & Santos, 2006). Besides these Deaf students, the participants we focus in were their classmates, their mathematics and special education teachers. We focus on the data collected in the first year of this research: from November (middle of the first term) to June (end of the school year) using informal conversations, observation (recorded in the researcher's diary and sometimes audio taped), students' protocols and documents. Interviews were conducted in November and April (Deaf students, mathematics and special education teachers). The data treatment and analysis was based in a narrative content analysis (Clandinin & Connelly, 1998), from which inductive categories emerged (Cesar, 2009), illuminating these Deaf students school paths.

Through the analysis of empirical evidence we address adaptations made by their teacher that facilitated mathematics learning and allowed these students to give a meaning to mathematics (Bakhtin, 1929/1981). We acknowledge five interactive patterns we identified in these mathematics classes (Borges, 2009) and how they facilitated students' transitions (Zittoun, 2006), namely from the mainstream culture and knowledge to the Deaf culture and these students' daily knowledge. The adaptations made by their mathematics teacher and classmates helped these Deaf students becoming more included in their class, among their peers group and in the school community. The results illuminate a well-accomplished inclusion process, where these Deaf students became legitimate participants (Cesar, 2009). Both hearing and Deaf students emerged from this experience as more inclusive and aware future citizens.

PAPER PRESENTATION

Teaching children to read the clock: a matter of time?

Elise Burny, Ghent University, Belgium; Ningning Zhao, Ghent University, Belgium; Martin Valcke, Ghent University, Belgium

Considering the fact that many primary school children experience difficulties in the acquisition of clock reading skills, the present study scrutinizes the Flemish curriculum for clock reading, assessing the extent to which it effectively promotes children's acquisition of clock reading skills. By comparing Flemish students' outcomes to the clock reading abilities of Chinese children, who are taught to read the clock according to a different curriculum, the developmental sequence in clock reading that was defined in previous research, is reexamined. The results of this study indicate that children's development of clock reading skills is subject to both instruction and maturation. Based on the current results, it seems that the Flemish curriculum is geared to children's capabilities and needs and that an acceleration in the teaching of clock reading skills is not advisable. However, further research on the effect of instructional strategies is necessary in order to optimize the teaching of clock reading skills in primary education.

Learning how to tell time is an important subject in primary school mathematics that is addressed in nearly every grade of primary education. This is not surprising, as the ability to read the clock appears to be a very complex concept that takes teachers years to teach to their pupils and at the same time presents itself as a fundamental life skill that allows us to plan our daily activities, to get organized and to function in a society that is driven by time (Bock, Irwin, Davidson, & Levelt, 2003; Friedman & Laycock, 1989). Nevertheless, there has been little research upon the pedagogy of time in general, and clock reading in specific. As previous studies showed that children's ability to read the clock develops in an age-related manner, starting with hour times at the age of six, and followed by half hour times in second grade (age 7), five minute time in third grade (age 8-9) and eventually one minute clock times in grade four (age 9-10) (Andersson, 2008; Boulton-Lewis, Wilss, & Mutch, 1997; Case, Sandieson, & Dennis, 1986; Friedman & Laycock, 1989; Griffin, Case, & Sandieson, 1992), the curriculum for clock reading in most Western countries reflects this developmental sequence. However, as Hodkinson (2004) pointed out that we have continuously underestimated what young children can do and learn with regard to the concept of historical time and that the English curriculum for history is not adapted to children's capabilities, it is worthwhile to reexamine the mathematics curriculum in order to find out whether clock reading abilities are currently taught in the most effective way.

In order to define whether the present curriculum for clock reading is geared to young children's capabilities and needs, the present study compares the outcomes of two distinct curricula: (1) the Flemish curriculum, that builds upon the developmental sequence as suggested in previous research, and (2) the Chinese curriculum, that suggests to teach all clock reading skills in first grade of primary school. By means of the test results of 10959 Chinese and 784 Flemish primary school children in grades one to six, clock reading skills were compared for both countries, showing that Flemish children indeed acquire clock reading according to the previously described developmental sequence. Despite the different curriculum in China, Chinese children do not acquire clock reading skills at a younger age than Flemish children. Moreover, Chinese children's accuracy in clock reading gradually improves between grade two and five, without any additional instruction or practice after first grade. This implies that the developmental sequence, as described in previous research, is not primarily influenced by the curriculum but seems rather universal and that children's acquisition of clock reading skills is at least partially subject to maturation. Based on the current results, it seems that the present curriculum for clock reading is geared to children's cognitive development and should not be changed. However, a closer analysis of instructional strategies and classroom practices is necessary in order to define the impact of instruction on children's acquisition of and accuracy in clock reading.

PAPER PRESENTATION

Junior high-school students' meta-emotional knowledge during mathematical problem solving

Erik De Corte, University of Leuven, Belgium; Peter Op 't Eynde, University of Leuven, Belgium; Fien Depaepe, University of Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Over the past decade researchers in the field of mathematics education have become more and more interested in the study of motivational and emotional besides cognitive aspects of mathematics learning. With regard to emotions it is of special importance that students are able to control their emotions during learning and problem solving (De Corte, Op 't Eynde, Depaepe, & Verschaffel, in press; Durlak et al., in press). In this respect research suggests that similar to metacognition, the self-regulation of emotional processes requires students to acquire emotional knowledge and skills that will enable them to become aware of their emotions and to actively regulate them. However, so far research has paid scarce attention to students' awareness and mastery of relevant meta-emotional knowledge and skills. This paper will report an investigation that attempts to analyze students' awareness and identification of their emotions during mathematical problem solving. Sixteen junior high-school students solved 4 complex mathematical problems. They were asked to think aloud during the solution process that was videotaped. Immediately after solving a problem a video-based stimulated recall interview took place. A cyclical procedure of data

analysis took place based on the thinking aloud protocols, the videotapes and the interview transcripts, and resulted in the identification of students' knowledge of emotions. The results that will be presented reveal that students possess some meta-knowledge that enables them to identify and describe their emotions. But the findings show also that they are often not immediately aware of the emotions they are experiencing.

Theoretical background and objective

Over the past decade researchers in the field of mathematics education have become more and more interested in the study of motivational and emotional besides cognitive aspects of mathematics learning. With regard to emotions it is of special importance that students are able to control their emotions during mathematical learning and problem solving (De Corte, Op 't Eynde, Depaepe, & Verschaffel, in press; Durlak et al., in press). In this respect research suggests that similar to metacognition, the self-regulation of emotional processes requires students to acquire emotional knowledge and skills that will enable them to become aware of their emotions and to actively regulate them. However, so far research has paid scarce attention to students' awareness and mastery of relevant meta-emotional knowledge and skills. This paper will report an investigation that attempts to analyze students' awareness and identification of their emotions during mathematical problem solving.

Method and data sources

Sixteen Flemish junior high-school students (age 14 years) of 4 classes in different schools were asked to solve in each of 4 consecutive lessons a complex realistic mathematical problem. They were asked to think aloud during the problem-solving process that was videotaped. Immediately after finishing a problem, a video-based stimulated recall interview took place (Prawat and Anderson 1994). In phase 1 of the interview the student and the researcher watched the videotape and the student was asked to recall what he did, thought, and felt while he was solving the problem, especially during those episodes that he was not thinking aloud. After the student had described in his own words his complete problem-solving story, the interviewer asked questions for clarification in phase 2. Episodes that seemed to be emotionally loaded were played back on the video. In view of the identification of emotions a stepwise technique of questioning was used. The researcher would first repeat the open question of phase 1. If the student's answer was not explicit enough in relation to possible emotions experienced, the researcher would explicitly ask "How did you feel?". If there was still no clear labeling of the emotion experienced, the researcher would proceed and check his own interpretation, asking, for example, "Did you feel angry?". A cyclical procedure of data analysis took place based on the thinking aloud protocols, the videotapes and the interview transcripts, and resulted in the identification of students' knowledge of emotions through a triangulation of the following data: facial expression, bodily actions, vocalizations observable in the videotape, and interpretations and appraisals explicated in the interviews. ResultsThe main findings summarized here below will be discussed in more detail during the presentation at the conference. Students experienced different emotions during problem solving. They felt at times annoyed, frustrated, angry, nervous, worried, anxious, relieved, happy, confident. Emotions were usually experienced at moments that students were unable to solve a problem as easily or fluently as they anticipated. Experiencing the inadequacy of cognitive strategies used, is apparently as much an emotional as a (meta-)cognitive process (see also Mandler 1989). However, students usually had a hard time in clearly describing the emotions they experienced. From the emotions observed in the episodes that were explicitly discussed with students in phase 2 of the interview, the large majority was not immediately and clearly identified by them. Only "relief" and "nervous" are emotions that - when experienced by students - were easily recognized and identified (resp. in 50% and 45% of the cases). The emotions "happy", "annoyed", "angry", "worried" and "anxious" were mostly only acknowledged and identified by students when they were explicitly asked to tell how they felt in an episode. Finally, "confident" and "frustration" were in respectively 83% and 60% of the episodes concerned only labeled by the students in confirmation of the interpretation of the researcher, and thus not spontaneously mentioned previously in the interview.

Conclusion, discussion, and direction for continued research

This study shows that students possess some meta-emotional knowledge during mathematical problem solving in the classroom. However, one can question if they are really aware of the emotion when they encounter it and act mindfully upon it. Indeed, in very few emotionally loaded episodes students described immediately the emotions experienced. Of course, it is possible that some students were aware of their emotions, but did not mention them by themselves in the interview. Also, one might argue that some students were possibly prompted to identify a selected episode as emotional because of the questions asked. We were well aware of these possible biases and, therefore, we presented only episodes to the students that indicated an emotional loading based also on other criteria than what the student said (e.g., facial expression, vocalizations, bodily gestures). However, in view of solving these methodological problems, an important challenge is to develop more sophisticated research methods that combine the use of psychophysiological and interpretative methods. Implications for educational practiceThe study documents that students do not acquire thorough meta-emotional knowledge spontaneously. Taking this into account but also the fact that appropriate self-regulation of emotions is a characteristic of productive learning and problem solving, it is

a challenge for mathematics education to foster in students identification and awareness of their emotions. Therefore, it is important that during the mathematics lessons teachers help students from time to time to develop meta-emotional knowledge and thus to become aware of their emotions in view of being able to regulate them constructively. In fact this also constitutes an issue for further inquiry, but some relevant ideas for educational practice have already resulted from research on the impact of social and emotional (SEL) programs (see Durlak et al., in press).

Rational number and proportional reasoning in Year 7 classrooms: Why dialogic teaching may not always contribute to student learning

Christine Howe, University of Cambridge, United Kingdom; Stefanie Luthman, University of Cambridge, United Kingdom; Riikka Hofmann, University of Cambridge, United Kingdom; Kenneth Ruthven, University of Cambridge, United Kingdom

Covering four key topics in mathematics and science, the ESRC-funded epiSTEMe project aims to promote student attitudes and achievement during Year 7 of the UK education system. This paper focuses on the trialling in six classrooms of a six- (optionally eight-) lesson module on one of the topics, rational number and proportional reasoning. Attitudes were assessed via post-module questionnaires, and were positive. Achievement was assessed via pre-tests before the module and post-tests immediately and four-weeks afterwards: pre- to immediate and immediate to four-week progress both occurred (unlike control classes taught by traditional methods where post-test scores were equivalent to pre-test). The positive results were consistent across the six classes, despite considerable variation in the implementation of the dialogic teaching methods that are central to the epiSTEMe approach. This has significant implications for how dialogic teaching should be theorized.

Located within the ESRC's Targeted Initiative on Mathematics and Science, the epiSTEMe project (Effecting Principled Improvement in STEM Education) seeks to promote student attitudes and achievement during Year 7 of the UK education system. Covering mathematics and science, the project emphasizes dialogic teaching methods, while also calling upon cognitive research into the development of reasoning. It began in 2008, will end in 2012, and comprises three main phases. The key activities for Phase 1 involve collaboration with teacher co-researchers from a small number of schools to devise a teaching intervention, which is grounded in four topic modules: a) fractions, ratios and proportions; b) probability; c) forces and proportional relations; d) electricity – electrical circuits. In Phase 2, the focus is upon classroom implementation by the teacher co-researchers, with results evaluated and modules refined. Phase 3 revolves around scaled-up implementation of the modules with a large sample of teachers who are new to the project, and controlled comparison with the established practices of a comparable group of teachers.

This paper focuses on Phase 2 implementation of the fractions, ratios and proportions module. The module is designed to occupy six 50-minute lessons (with an optional further two lessons), and has many features that differentiate it from standard Year 7 teaching. Unusually with this age band, the module uses proportional reasoning to contextualize the teaching of rational number (decimals and percentages as well as fractions and ratios). At the same time, it emphasizes equivalences across decimals, percentages, fractions and ratios as much as equivalences within these differing types of number, e.g. between simplified and non-simplified fractions. Current and historical events are used to highlight the topic's relevance to everyday life. Finally, the module employs an integrated series of small-group and whole-class activities, all of which emphasize the articulation, justification and resolution of contrasting viewpoints in a dialogic environment.

Six classes were involved in Phase 2 implementation of the fractions, ratios and proportions module. All classes involved Year 7 students of approximately 12 years of age. Four classes were located in English secondary schools and were streamed by mathematical ability (top to middle sets), and two classes were located in Scottish primary schools and were mixed ability. In all cases, the students: a) took a pre-test during the first lesson; b) proceeded through the lessons (observed and/or video-recorded while they did this); c) took an 'immediate post-test' during the final lesson and completed a 'learning perceptions' questionnaire to indicate their attitudes towards the module; d) (in four classes) took a 'deferred post-test' four weeks later. Pre- to immediate post-test gain occurred in all six classes, and additional immediate to deferred post-test gain occurred in three of the four classes to complete both tests. The extent of gains was consistent across classes. The gains contrasted with results obtained from two control classes, who studied fractions, ratios and proportions using traditional methods: here post-test scores were equivalent to pre-test scores. In addition, the students in the six Phase 2 implementation classes expressed generally positive attitudes in response to the learning perceptions questionnaire.

While it was encouraging to witness pre- to post-test gains with all six Phase 2 implementation classes, the consistency of these gains across the classes was in some respects surprising. This is because classroom observations

indicated marked variation in how effectively the dialogic component was implemented. At one extreme, research literature ideals were reached; at the other extreme, dialogic interaction was virtually non-existent. A possible interpretation is that in these six classes, talk was not regarded as the locus of teaching; the focus was on module materials, and it was these materials that promoted learning. One general implication would be that good dialogue alone is insufficient for effective teaching; the relevance of dialogue also needs to be highlighted for students. This carries an important message for both the implementation of dialogic methods and for the criteria by which good practice is identified during teaching observation.

PAPER PRESENTATION

The development of critical thinking in first year educational sciences students

Sigrid Francois, KULeuven, Belgium; An Verburgh, Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium

Critical thinking is an important aim in higher education. This is also the case for higher education in Flanders (Belgium). Despite its importance, empirical data on students' growth in critical thinking are mainly limited to the Anglo-Saxon area. Data on the development in continental Europe are scarce. To gain insight in the situation in Belgium, a study was conducted among a cohort of 171 first year bachelor students in an educational sciences programme. A test constructed with items from both the Halpern Critical Thinking Test in Everyday Situations and the Cornell Critical Thinking test was administered twice: a first time at the beginning (November) and a second time at the end (May) of the academic year. A paired sample t-test shows a significant growth in critical thinking between the first and the second administration of the test. Furthermore, students with a higher first time score show less growth in critical thinking than their peers with a lower first time score. In addition the relation between growth and the option followed in secondary education was looked at. Results of this analysis show students who choose stronger options during their prior education tend to score higher for critical thinking. In the paper these results are discussed from a methodological and theoretical perspective and suggestions for future work are made.

Introduction and aims

Worldwide, the development of critical thinking is acknowledged as an important aim of higher education (King & Kitchener, 2004). Also in Flanders (Belgium), policy documents as well as empirical data indicate that the development of critical thinking is an important objective. Verburgh, Schouteden and Elen (2009) showed that the development of critical thinking is the most frequently mentioned course and programme goal. Their study indicated however that it was a vexed educational goal, difficult to grasp its meaning and unclear how it relates to other goals. Studies on critical thinking performance show (1) differences in students' critical thinking skills between the start and the end of their undergraduate studies, and (2) overall students often do not reach highest levels of critical thinking (Astin, 1993; Giancarlo & Facione, 2001; Miller, 1992). Empirical data are mainly based on Anglo-Saxon students and studies on the Belgian/ Flemish students are lacking. This study investigates first-year students' growth with respect to critical thinking among students in an educational sciences bachelor programme at a Belgian university. It analyses differences in critical thinking performance between the beginning (November) and the end of the academic year (May). Critical thinking performance is expected to grow between the beginning and the end of the academic year.

Methodology

In the study, an online-test is used consisting of translated items of two different critical thinking tests (the Halpern Critical Thinking Assessment (Halpern, 2007) and the Cornell Critical thinking test, level Z (Ennis, Millman, & Tomko, 1985)). The selection of the items is based on a factor analysis and on content validity (for more information: see X). The test consists of 17 situations, followed by an open and/or closed question about that situation. In order to answer the question, critical thinking is required. The test consists of 34 items. Most open questions are subdivided in two parts (e.g.; 1. What is the best evidence provided that supports the director's claim? 2. What is the best evidence to refute the claim?). The maximum score is 95. One cohort of first year students, in the bachelor educational sciences of the K.U.Leuven filled out the test twice, once in November '09 and once in May '10, as a compulsory part of a course. The test was administered collectively. In November 171 students filled out the test, in May there were 158 students, of which 153 students were the same students as in November. All open questions were independently scored by two raters. The agreement between these two raters on the different parts of the questions is acceptable to almost full agree (only one question lower than 70% agreement (i.e. 62%), 5 subquestions between 70 and 80%, and the 19 others 80% or higher. All different scores were discussed until agreement was reached. The reliability of the test is acceptable for a complex construct such as critical thinking (Cronbach alpha= .65).

Findings

A paired-sample t-test was conducted to evaluate students' growth in critical thinking. There was an overall statistically significant increase in critical thinking performance between November ($M=57.86$, $SD=7.67$) and May

($M=61.69$, $SD= 8.07$, $t=-6.27$; $df = 152$; p . To gain insight into the relations between growth, November-score and May-score Pearson-product correlation coefficients were calculated. November and May-scores are positively correlated ($r=.54$). Growth is negatively correlated with critical thinking performance in November ($r=-.44$). The higher students score in November, the less they grow. Growth is positively correlated with critical thinking performance in May ($r=.52$). To investigate the relationship between critical thinking performance and secondary education, a mixed between-subjects analysis of variance was conducted, with November and May-scores as within-subject variables (time) and type of secondary education as between subject factor (very strong option in secondary education, a strong option and a option in human sciences. There is significant growth between November and May, $F(1, 141)=38.92$, p Theoretical and educational significance of the findings. This study is one of the first to explore growth in critical thinking in a non-Anglo-Saxon area. The findings demonstrate that Belgian first-year university students in educational sciences grow in their critical thinking performance. In addition, evidence was found that students who score weaker in the beginning show more growth. We also found that the option followed in secondary education at least partially explains differences in critical thinking between students, but it does not explain their growth in critical thinking during their first year at university. The findings confirm earlier research in Anglo-Saxon countries which demonstrate growth in critical thinking (e.g. Giancarlo & Facione, 2001). Test -retest effects are rather unlikely because students who only participated in May do not strongly differ from the others. More probably, the educational setting stimulates students to develop their critical thinking ability, because the setting has characteristics that were identified in previous research to elicit development in critical thinking, such as discussing in groups, write assignments, essay exams... (e.g.; Tsui, 1999) However, further work is still needed to clarify what factors in the educational setting contribute to growth in critical thinking in higher education and to explain why there is a smaller growth in high-achievers. In order to do so, future studies need to take more programmes and students in different stages in their programme into account, along with a fine-grained analysis of the educational settings in these programmes. A longitudinal design, over different years would shed light on the actual development over different years. The current research shows this test is suitable for such a purpose because there is ample space for growth.

PAPER PRESENTATION

Epistemic beliefs of high school students: "Can we trust the news about Haiti?"

Florian Feucht, The University of Toledo, United States; Nathan Ziegler, The University of Toledo, United States; Lauren Maziarz, The University of Toledo, United States; Susan Hany, The University of Toledo, United States

Over the last decade, technological advancement has made global news more accessible for learners than ever before. Despite this accessibility, students are not provided with a framework to critically analyze the news, especially on a global scale. The capacity of teenagers to form opinions and make decisions about the news does not come naturally, nor does their appreciation of the cognitive labor involved in these processes. Hence, there is the need for teenagers to acquire the skills for and value of being critical global news consumers. This research study explored the news seeking behavior of teenagers ($n = 60$; mean age 17.6, $SD 0.76$) applying a combination of interview and observation techniques. Twelve participants were interviewed specifically about the earthquakes in Haiti and their news seeking behavior in this context (i.e., espoused beliefs). Then, they were asked to assess the credibility and quality of several newspaper clippings on the earthquake of Haiti (i.e., enacted beliefs). Results showed that more than 60% of the students were not able to apply criteria and strategies to assess the quality and credibility of the news clippings. Essentially, young adults should be cognizant of criteria and strategies to assess global news, be able to form their own opinions, and be able to verbally argue for their opinions. Results demonstrate the need for educators to develop educational materials and interventions to improve the skills necessary to critically analyze global news in addition to improving opinion forming skills related to these issues.

Introduction

Students in the 21st century have access to more information than any generation before them. Often, they are confronted with news from online news sources, social networking sites (i.e., Facebook, Twitter), the television, newspapers, magazines and the radio. Even though there is a plenitude of news sources, students often confront very contradictory information from these sources. Since news is always streaming from multiple sources simultaneously, students need to possess the skills to critically analyze the news media and make informed decisions about the content. For example, what were the students' understandings of the earthquakes in Haiti? How did students analyze the different news articles and sources and form an opinion? Did the students find an article that matched their existing beliefs and schemas and believe that this article was providing factual information? The answers to these questions are increasingly pertinent to education, and with the growing connectedness in today's global society, students need to be inclined to critically analyze news media. Thus, this study explored high school students' epistemic beliefs on an a priori news issue: the earthquakes in Haiti.

Theoretical Framework

Epistemic beliefs can be defined as subjective theories a person holds about the nature of knowledge and knowing (e.g., Hofer, 2001). These beliefs revolve around certainty of truth, origins and sources of knowledge, and ways of justifying knowledge claims. Epistemic beliefs unfold along a developmental progression, ranging from naïve beliefs to sophisticated beliefs (e.g., Kuhn, 1999). Research has shown that sophisticated epistemic beliefs have a positive influence on reasoning skills, critical thinking skills (e.g., Kuhn, 1999) strategy use and ethical and intellectual development (e.g., Schommer, Crouse & Rhodes, 1992). Furthermore, Kuhn (1991) and Weinstock and Cronin (2003) found that people with sophisticated beliefs are more likely to identify evidence in written accounts, to analyze argumentations, and take less extreme positions. These findings align with Kuhn's (1999) developmental framework for critical thinking. For this study, we adapted Kuhn's (1999) framework by focusing it on "news" as a specific knowledge source rather than "knowledge" in general.

Research Questions

The directing research questions were: What are the epistemic beliefs of high school students about news, specifically to the earthquake in Haiti? What criteria and strategies do students state they would apply when analyzing the quality and accuracy of written news? What criteria and strategies do students actually apply when analyzing the quality and accuracy of written news articles?

Methods

Sixty high school students from a rural Midwestern high school in the United States were interviewed. Participants were drawn from 11th and 12th grade classrooms with an even gender distribution. The materials encompassed a set of semi-structured interview questions and a sorting task. The semi-structured interview targeted beliefs about news quality, strategies, and criteria used to evaluate news in general. More specifically, a group of students were interviewed about the devastation that struck Haiti in early 2010. In the sorting task participants were asked to read, sort, and categorize five news clippings about Haiti. The clippings differed in perspective and degree of providing facts, opinions, and formatting. The researchers pulled students from their classroom for one-on-one data collection in the school library, and lasted approximately 40 minutes. The method of qualitative content analysis was used to summarize, explicate, and structure the qualitative data. The software, Atlas.ti, was used in this process.

Results

Preliminary analyses of data identified discrepancies between what students say (interview) and do (sorting task). Some students mentioned strategies and criteria but were not able to apply them while others were able to apply criteria and strategies but were not cognizant about them. More than 60% of the students were not able to apply criteria and strategies to assess the quality and credibility of news clippings about the earthquakes in Haiti. From an educational standpoint, young adults should be cognizant of criteria and strategies to assess scientific and environmental news, be able to form their own opinions, and to verbally argue for their opinions. Most high school students did not trust the news as a source of knowledge. They believed its primary goal was to manipulate facts in order to influence public opinion.

Conclusion

Based on our results, it is evident that there needs to be more focus on developing students' epistemic beliefs so that they are able to critically analyze the news media. As research has shown (e.g., Kuhn, 1999), critical thinking skills do not develop naturally. Students must be scaffolded to more sophisticated levels of thinking and must be provided with a framework from which they can analyze the news media. Even though our results are not generalizable across a large population, we believe that this study offers insight into the nature of high school students' epistemic beliefs, their beliefs about news media, and their understanding of global issues such as the earthquakes in Haiti.

PAPER PRESENTATION

Learning about the Equal Additions strategy for subtraction by Year 5/6 students

Jennifer Young-Loveridge, University of Waikato, New Zealand

The purpose of the study was to investigate interactions between teachers and their students during a mathematics lesson designed to teach the Equal Additions strategy for subtraction. Nine teachers (7 females and 2 males) and a total of 64 Year 5/6 students (9- to 11-year-olds) participated in the study. The language of the teachers and those students closest to them were audio-recorded and observational notes made of non-verbal information. The transcripts for the Equal Additions lesson were analysed both quantitatively and qualitatively. Two teachers (C and G) appeared to be particularly effective in teaching the Equal Additions strategy, and they each had two students who used the strategy during written assessment. What distinguished these two teachers from the others was their understanding of the purpose of the lesson and the strong conceptual understanding of mathematics that was clearly evident during their interactions with the students. The results reflect the challenges of bringing about deep and lasting change in the ways that mathematics is taught and learned, when there is a strong emphasis on building students' conceptual understanding rather than simply training them in mindless procedures and skills.

The purpose of the study was to investigate interactions between teachers and their students during a mathematics lesson designed to teach the Equal Additions strategy for subtraction (see Ministry of Education, 2008a, Book 5, pp. 38-39). The lesson was the second of three lessons taken from the resource materials of New Zealand's Numeracy Development Project, a major initiative designed to raise students' achievement in mathematics (see Ministry of Education, n.d.). Nine teachers (7 females and 2 males) and a total of 64 Year 5/6 students (9- to 11-year-olds) participated in the study. Each teacher chose the instructional group for which the three lessons seemed most appropriate in terms of their current stage on the New Zealand Number Framework (Ministry of Education, 2008b). The lessons were designed to consolidate students' understanding of number properties within the domain of addition and subtraction (stage 6 Advanced Additive Part-Whole thinking). Instructional groups ranged in size from 5 to 10 students. Prior to the first lesson and after the third lesson, students were given a brief paper-and-pencil assessment that asked them to show their solution strategy for each answer. On the post-test, only 8 of the 64 students used the Equal Additions strategy to solve a problem. Two of the teachers (C and G) had more than one student in their group that used the strategy (4 others had one student each). During the lessons, each teacher wore a portable digital audio-recorder attached to a flexible belt, with lapel microphone to record his/her language (and that of students who were close to teacher). The researchers observed the lesson and noted non-verbal (contextual) information that could assist with the interpretation of the transcripts of audio-recordings.

Although the first lesson, Saving Hundreds, is not the focus of this paper, the experience of working with missing addend problems such as $\$287 + ? = \400 the previous week, helped to familiarise the students and their teacher with being observed and recorded by the researchers. Saving Hundreds also introduced the use of paper money (in denominations corresponding to place value units), an important component of the Equal Additions lesson. Another key aspect of the Saving Hundreds lesson was the experience of exchanging ten \$1 notes for one \$10 note, and vice versa, and this provided an important introduction to the contexts used for the Equal Additions lesson.

In the Equal Additions lesson, the first problem is a comparison problem, as follows:

Problem: "Debbie has \$445 in her bank account, and her younger sister Christine has \$398. How much more money does Debbie have?"

Make piles of \$445 and \$398. "Now suppose that Grandma gives Christine \$2 to give her a 'tidy' amount of money. To be fair, Grandma gives Debbie \$2 also." Discuss why $445 - 398$ has the same answer as $447 - 400$ and then record $445 - 398 = 47$ on the board or modelling book.

The teacher's book then presents other problems to be solved using materials (eg, paper money).

The transcripts for the Equal Additions lesson were analysed both quantitatively and qualitatively. Using the approach of Mercer and Littleton (2007), the frequencies of particular "indicator words" (why, how, which, what, cause, think, agree, if) were calculated for each teacher. Although frequencies for each of these words varied, neither Teacher C nor Teacher G differed notably from the other seven teachers in their use of these words. The transcripts of teachers C and G were examined closely, along with the observational records. What distinguished these two teachers from the others was their understanding of the purpose of the lesson and the strong conceptual understanding of mathematics that was clearly evident during their interactions with the students. For example, they both understood that the purpose of adding an equal quantity to both the minuend (larger number) and the subtrahend (smaller number) was to "tidy" the subtrahend up to a round number that could be easily subtracted from the minuend. Some other teachers were not aware of this and encouraged their students to "tidy" whichever number they preferred. When students tried to "tidy" the minuend, it did not make the calculation any easier. In post-lesson interviews, the teachers all expressed confidence that their students had understood the Equal Additions strategy. However, the researchers were not convinced that the students really understood the strategy. Teachers C and G appeared to be the most successful teachers. Although the teachers asked their students to explain their solution strategies, they accepted these explanations very readily, without pressing students to prove why the strategy worked. Students were not asked

to compare the Equal Additions strategy with other popular strategies for subtraction such as Rounding and Compensating, Bridging Through Ten/s, Reversibility, or the standard written algorithm so students were not aware of the elegance and efficiency of this particular strategy. Most teachers were committed to enhancing conceptual understanding but seemed unaware that their approaches were quite procedural. It was interesting to note that none of the teachers drew students' attention to different problem structures for subtraction, or contrasted the use of subtraction to calculate difference rather than to "take away." The findings have some important implications for the field of conceptual change, specifically students' understanding of mathematics, as well as teachers' content knowledge and pedagogical content knowledge for mathematics. The results reflect the challenges of bringing about deep and lasting change in the ways that mathematics is taught and learned, when there is a strong emphasis on building students' conceptual understanding rather than simply training them in mindless procedures and skills. The findings are considered in relation to constructivist and socio-cultural theories.

PAPER PRESENTATION

Effects of instruction considering individual students' conceptions of vision and perception

Sarah Dannemann, Freie Universitat Berlin, Germany

Many studies have determined the importance of students' conceptions for learning (c.f. the bibliography of students' and teachers' conceptions, Duit 2003). However, it is not enough to know about the various students' conceptions that exist. Knowing about the individual conceptions of students in class opens up the opportunity to use them as anchors for a specific and individual learning. The aim of this research project is to determine if learning can be advanced when teachers consider individual students' conceptions explicitly in class, and if this kind of learning has a lasting effect in terms of conceptual changes. To test this, an intervention study (N = 215) with three conditions is conducted: one intervention group in which individual students' conceptions were considered and two control groups. In the first control group all students get the same material as the intervention group but teaching is not considering their individual conceptions. The second control group is not instructed. All groups are tested three times with a diagnostic computer program for students' conceptions of vision and perception (Dannemann & Krýger 2009, 2010). In the intervention group, epistemic and metaconceptual conceptions were also addressed and discussed. Preliminary results show that students whose individual conceptions are explicitly considered in class are modifying their everyday conceptions significantly more often.

Students' conceptions are mentioned as one of the most important factors of learning. In many studies students' conceptions were analyzed and described for different topics using interviews, group discussions or open-ended questionnaires (e.g. Guesne 1992; Gropengießer 2001 concerning vision and perception). Different learning arrangements and guidelines were created (e.g. Gropengießer 2006; Duit, Treagust & Widodo 2008). However, it is not enough simply to know students' conceptions concerning one topic. What is helpful for one student can consolidate everyday conceptions of others. Therefore, it is important to know the individual students' conceptions and to teach them accordingly.

The aim of this study is to determine if learning can be advanced when teachers consider individual students' conceptions explicitly in class, and if this kind of learning has a lasting effect in terms of a conceptual reconstruction. In recent years, emphasis was laid on the role of epistemic beliefs and metaconceptual conceptions that contribute to the process of learning (Murphy 2007; Vosniadou 2007). Therefore, epistemic beliefs and metaconceptual aspects are also included in the learning arrangements.

This study is based on moderate constructivist epistemology (Reinmann & Mandl 2006). Learning arrangements are created in a way that they summon students to become aware of their initial conceptions and to reflect them and discuss them with others.

The framework of this study is the Model of Educational Reconstruction (Kattmann 2007). Students' and scientific conceptions are seen as equally valid and useful sources of individual sense making.

The theory of Conceptual Change describes processes in which students' understanding is modified or refined so that students' conceptions are approximating scientific conceptions (Strike & Posner 1992). To point out that students' conceptions do not change in learning processes but get modified the term 'conceptual reconstruction' is used in this study (Krýger 2007). As Vosniadou (2007) points out, not isolated misconceptions need to be reconstructed but domain-specific theories based on everyday experience.

This study focuses on these main research questions:

- To what extent does (constructivist oriented) instruction that explicitly considers individual students' conceptions support learning processes of vision and perception?

Hypothesis 1: The students of the intervention group will acquire scientific conceptions more often and will be more sure about them than students that have not been taught accordingly to their individual conceptions.

- To what extent does this way of learning has a lasting effect?

Hypothesis 2: The students of the intervention group are able to create metaconceptual awareness, so they should be able to use their scientific conceptions in adequate contexts even after some time has passed.

The study is designed as a pre-post-follow-up-testing. Three different learning environments are compared:

Group I: The identified individual students' conceptions of the intervention-group were considered, giving them learning material that referred explicitly to their individual conceptions, and discussing different coexisting conceptions and metaconceptual aspects.

Group II: Students of this control-group learned with material that did fit to their individual conceptions just by chance. All students got material that was created for the most common conceptions. Besides, the individual students' conceptions are not known by the teacher.

Group III: The second control-group was not instructed on vision and perception.

Each learning environment was tested in three classes (8th and 9th grade (N = 215)).

Please insert picture 1.

To determine students' conceptions, a diagnostic inventory for conceptions of vision and perception was used (Dannemann & Krýger 2009, 2010). It is designed as a computer program with 17 tasks in a multiple-choice-format. The tasks include different themes e.g. the role of light, the eyes, and the brain in the seeing process, image formation and even epistemic conceptions of everyday realism or constructivist ideas of oneself and the external world. For each conceptions students are classified either as 'sure', 'not sure', or 'rejecting'. Reading competence (LGVT 6-12, cf. Schneider et al. 2007), motivation concerning biology as a school subject and concerning the topic of vision and perception (PISA 2006-scales, cf. Prenzel et al. 2007) were tested as additional variables, and some personal data (grades, methodical skills) were collected.

Group I and group II were instructed for four lessons, mainly conducted in rotation work in groups of 3 to 4 students with similar conceptions. At the end of each lesson, students' ratings of features of constructivist instruction (Urhahne et al. 2010) were determined.

The presented results are preliminary because the complete data is not evaluated yet.

Table 1 shows the results of the pre- and the post-test of three classes for the conception "instruction" which means the scientific idea of "light reflects from the object into the eye". Only students who changed or refined their conception after the treatment are mentioned. Some students had instructionist ideas before and retained them (group I: 7 students (n = 24); group II: 4 students (n = 21); group III: 5 students (n = 22)). The others had everyday conceptions before and after the treatment.

Table 1. Students who changed their belief in the conception "instruction" from the pre- to the post-test in group I (Int.), group II (Contr. 1) and group III (Contr. 2); * = significance with 0,05.

Please insert table 1.

9 students out of the intervention group have changed from an everyday conception to the scientific one, 1 student is not sure. In the first control group, only three students reconstructed their everyday conceptions and in the second control group just one person is not sure about "instruction" in the post-test. The differences between intervention group and control groups are significant. This result supports hypothesis 1.

These results show that students of the intervention group have modified their conceptions of this theme significantly more often than students of both control groups. Concerning the epistemic conceptions the results are not as clear.

Most students are keeping their former concepts or are just changing from 'sure' to 'not sure'. Epistemic ideas might need more time to be modified. There might be a bigger effect in the follow-up-test. The complete results of this study will be available at EARLI 2011.

PAPER PRESENTATION

Visual carbon cycle narratives in diagram form have translation traps

Simon Gates, University of Exeter, United Kingdom

The visual literacy of narratives for the carbon cycle topic in secondary school science in England, as displayed in diagrams, was investigated in an interpretive study. A selection of diagrams was used by informants at interview. Published instructional diagrams were also evaluated: 43 diagram designs were of interest. In all, the creations of over 200 educators were inspected. The study uncovered a widespread occurrence of diagrams with visual literacy faults, both in school texts and exam papers in England, over the last 40 years: evidence that they did not have visually-literate makers. Little has been reported in the literature about the visual literacy, narrative version, diagram form, or accuracy of these diagrams. It seems to be assumed, wrongly, that published diagrams will have accurate content and be visually literate; that teachers and pupils will use them without difficulty. The findings presented here show that although these diagrams can be made so they translate precisely into speech and written English, informants did not do this easily. The results revealed a number of translation traps. These, and the evidence for them, are presented in detail. They inform strategies for using diagrams in ways that avoid them, are introduced.

The aim of this qualitative research has been to explore, with educators, issues of visual literacy, design, content and use of diagrams available to teach the carbon cycle topic to secondary science pupils aged 14-16 in England, as part of our National Curriculum. Research questions were general: How do educators see and use carbon cycle diagrams? What do they notice, like and dislike about them? How do they use their own, and how would they use ones made by others?

The methodology for this empirical, interpretive-constructivist study, (Schwandt, 1994), was modelled on a naturalistic approach, and contained elements of multiple case studies (Bassey, 1999). Two instruments were used. First, semi-structured interviews with an opportunistic selection of educators, focused on tasks set with carbon cycle diagrams selected from textbooks and exam papers. This was followed by an archival survey of the content, structure, and accuracy of carbon cycle diagrams published in textbooks and exam materials. Its focus was informed by the first instrument. The informants, and the outputs of other diagram makers, together, provided evidence about carbon cycle narratives produced by over 200 education professionals, most in the UK; others in Europe and the USA. Informants were asked to evaluate carbon cycle diagrams, carry out tasks with them and say how they might use them in their own teaching. Informant talk, recorded at interview, the transcripts, and diagrams the informants made, were coded for themes. These were collected into categories, and then transformed and evaluated to present the findings. A number of criteria were used to provide reliability, and generalizability (Taylor and Wallace, 2007). Importantly, each of the two instruments did provide evidence which reinforced and complimented the findings of the other.

Findings

In general, informants preferred diagrams which contained naturalistic depictions. They commented on surface features, not those to do with narrative version, accuracy of content, the visual conventions used, or form and its implications for using these visual narratives with pupils. Many flaws in design or content went unremarked. They disliked exam diagrams, which had little supporting text to aid translation of the processes linking the entities, and had narrative versions and forms with which they were unfamiliar. Carbon cycle diagrams can translate precisely into speech and formal writing, but informants did not translate them into speech easily. Indeed, some had limited experience of using published diagrams. In particular, the strategies informants used for translating process arrows in these diagrams exposed translation traps for teachers, writers of text matching or using diagrams' visual narratives, and for pupils. These are presented and discussed in detail, with the aid of a reference model of a carbon cycle narrative. To avoid these traps, teachers need to see diagrams in particular ways, use the right strategies to translate them into speech, and instruct pupils how to translate between visual narratives and speech or writing. Educational significance. No direct reference is made to this problem in the literature, but the way some writers construct expository text for pupils indicates they are aware of it (See Mackean 1978, for example). The presentation will show that exposing the problems informs a useful training specification to provide for accuracy and fluency in the visual literacy required for more effective instruction with carbon cycle diagrams, a topic which is of interest to all of us, now that we are confronted with changing carbon dioxide levels and their consequences (Fýssel, 2009). These diagrams can also be used to make accurate templates to teach other cycles: water, nitrogen, and oxygen, for example. More generally, Avgerinou gives a current perspective on the universal importance of visual literacy. Pauwels describes what we need for practical, everyday, 21st century 'visuality'. This study provides a case in point. Without it, we cannot

teach, learn, or function adequately in or out of school, in our contemporary, global, visual culture. Visual literacy is a fundamental requirement for unambiguous communication using any and every medium in a globally networked world.

PAPER PRESENTATION

The Impact of Feedback on Mathematical Competencies

Birgit Harks, German Institute for International Educational Research, Germany; John Hattie, The University of Auckland, New Zealand; Katrin Rakoczy, German Institute for International Educational Res, Germany; Eckhard Klieme, Deutsches Institut für Intern. Pädagogische Forschung, Germany

The powerful impact of feedback on learning has been demonstrated in many studies. However, to date, only few researchers have dealt with the influence of feedback on mathematical achievement in secondary school. In the present study we compare the effects of two kinds of feedback on mathematical competencies of secondary school students and take a closer look on how these effects come about by investigating the role of motivational, cognitive, and meta-cognitive mediating variables. Our research questions are: (1) What impact does process-oriented feedback in comparison to social-comparative feedback have on the development of mathematical competencies? (2) Do motivational, cognitive and meta-cognitive variables mediate the impact of process-oriented vs. social-comparative feedback on the development of mathematical competencies? To investigate these questions a laboratory experiment with a one factor, bivariate design was conducted. 97 students were assigned to either process-oriented or social-comparative feedback. Mathematical competencies were assessed with tests, mediating variables were measured by questionnaires. Results of path analysis show that (1) process-oriented feedback has a stronger impact on the development of mathematical competencies than social-comparative feedback. (2) This comparatively positive impact of process-oriented feedback on mathematical competencies is mediated via cognitive, but not via motivational or meta-cognitive variables.

Theoretical Background & Aims

Since international comparative studies such as PISA (OECD, 2004) revealed low levels of mathematics achievement in secondary school students in many Western countries, educators, policy-makers, and researchers are faced with the challenging task of finding ways to enhance students' mathematical achievement. Latest research suggests that one important way of promoting students' learning is to provide students with feedback (e.g., Hattie, 2009). However, so far, most researchers have studied the impact of feedback by using tasks (like abstract memory or problem-solving tasks) which have little relation to the learning contents at school. The impact of feedback on mathematical achievement in secondary school has rarely been investigated (e.g., Rakoczy et al., 2008).

Feedback researchers argue that especially feedback which (1) uses an individual frame of reference (e.g., Shute, 2008), (2) provides information about task performance, process of understanding or self-regulation, and (3) helps to reduce discrepancies between current performance and learning goals (e.g., Hattie & Timperley, 2007) is beneficial for learning. However, a lot of feedback information actually given in mathematics classrooms, is neither individual-referenced – but social-comparative – nor elaborated in terms of directing students towards their learning goals. Considering these findings, one aim of our study is to compare the impact of elaborated and individual-referenced feedback (process-oriented feedback) with the impact of non-elaborated, social-comparative feedback (social-comparative feedback) on the development of mathematical competencies of secondary school students. With regard to mathematical competencies we focus on technical competence (competence to use knowledge about

mathematical facts and skills) and modelling competence (competence to transform a real world problem into a mathematical problem and vice versa).

A second aim of our study is to gain a deeper understanding of how different kinds of feedback affect the development of mathematical competencies. Cognitive, meta-cognitive and motivational variables have been identified as central components in the process of learning (e.g., Boekaerts, 1999). Butler & Winne (1995) point out that feedback can influence each of these components. As few empirical studies have investigated this assumption so far, we analyse the role of motivational, cognitive, and meta-cognitive variables in mediating the feedback effect on the development of mathematical competencies.

In summary, our research questions are (1) What impact does process-oriented feedback in comparison to social-comparative feedback have on the development of modelling and technical competence? (2) Do motivational, cognitive and meta-cognitive variables mediate the impact of process-oriented vs. social-comparative feedback on the development of modelling and technical competence?

Methods

A laboratory experiment with a one factor, bivariate design was conducted. 97 ninth graders from 55 classes in 23 German schools (intermediate secondary school track) were individually tested. Students were assigned to two feedback conditions. In the social-comparative feedback condition, individual achievement was compared with a social frame of reference by reporting the individual grade, the average grade and the overview of grades of a social reference group. In the process-oriented feedback condition, an individual frame of reference was used and information about strengths and weaknesses (regarding task performance, process of understanding or self-regulation) were given. Additionally, learning aids and strategies were provided to help students move towards their learning goals.

Modelling and technical competence were measured before and after the feedback. As an indicator of the development of modelling respectively technical competence (dependent variables) the difference between post- and pretest WLE-parameters for modelling respectively technical competence were used. Modelling competence and technical competence items covered a broad scope of content domains of mathematics instruction and were partly derived from the German national standards and partly developed in the context of the Co2CA-project (Conditions and Consequences of Classroom Assessment). Modelling and technical competence scales consisted of 15 pretest and 6 posttest items each (modelling competence: EAP-reliability = .67, technical competence: EAP-reliability = .71).

Motivational, cognitive and meta-cognitive mediating variables were measured by amotivation (4 items, e.g., "This test was a waste of time.", Cronbach's α = .70), behavioural adaptivity (5 items, e.g., "Feedback helps me to see where I can improve", Cronbach's α = .81), and accuracy of self-evaluation (amount of difference between a self-evaluation judgment on the overall test performance and the actual test performance).

After pretesting modelling and technical competence, feedback was given. Subsequently students' behavioural adaptivity, amotivation, self-evaluation, modelling and technical competence were assessed.

Data were analysed with path analysis using MPlus. We applied a model with feedback (process-oriented vs. social-comparative feedback) as a dummy coded predictor, behavioural adaptivity, amotivation and self-evaluation as mediators, and modelling and technical competence as criteria. Effects of feedback on the three mediators and effects of the three mediators on modelling and technical competence were specified. Additionally, an effect of behavioural adaptivity on amotivation was modelled. Total, direct and indirect effects were estimated.

Results

The path model yields a good fit to the data. Results reveal a total effect of feedback on modelling competence, not on technical competence. Furthermore, there is a direct feedback effect on behavioural adaptivity, but not on self-evaluation or amotivation. Behavioural adaptivity in turn has a direct effect on modelling competence, technical competence and amotivation. In contrast, neither self-evaluation nor amotivation influence modelling or technical competence. Accordingly, an indirect effect of feedback via behavioural adaptivity on modelling competence, technical competence and amotivation is shown. There is no indirect effect via amotivation or via self-evaluation.

Discussion

We conclude that: (1) Process-oriented feedback has a stronger impact on the development of modelling and technical competence than social-comparative feedback. (2) The comparatively positive impact of process-oriented feedback on modelling and technical competence is mediated via behavioural adaptivity, but not via amotivation or self-evaluation. Students who receive process-oriented feedback show a higher behavioural adaptivity than students

who receive social-comparative feedback. An increased behavioural adaptivity, in turn, leads to a greater development in modelling and technical competence and to a decrease in amotivation.

This study reveals that a shift in the existing feedback culture – in terms of providing more individual-referenced and elaborated feedback on strengths, weaknesses and learning aids – could be beneficial in helping secondary school students to enhance their mathematical competencies.

PAPER PRESENTATION

How Do Vocabulary Interventions Affect Young At-Risk Children's Word Learning: A Meta-Analytic Review

Loren Marulis, The University of Michigan, United States; Susan Neuman, The University of Michigan, United States

This meta-analysis examines the effects of vocabulary interventions on at-risk preschool and kindergarten children's oral language development. The authors quantitatively reviewed 39 studies and 112 effect sizes to better understand the impact of training on word learning. Results indicated an overall effect size of 0.94, $SE=0.10$ $CI95=0.74, 1.14$, $p<.01$, indicating, on average, a gain of nearly one standard deviation on vocabulary measures. Moderator analyses reported greater effects for trained adults in providing the treatment, combined pedagogical strategies that included explicit and implicit instruction, studies who targeted specific vocabulary words in advance of instruction and author-created measures compared to standardized measures. Middle- and upper-income at-risk children were significantly more likely to benefit from vocabulary intervention than those students both at risk and poor. These results indicate that although they might improve oral language skills, vocabulary interventions are not sufficiently powerful to close the gap—even in the preschool and kindergarten years.

Vocabulary at age 3 is strongly associated with reading comprehension at the end of grade 3, and predicts the trajectory of word acquisition that impacts future academic learning (Hart & Risley, 1995). However, there are significant differences in vocabulary knowledge among children from different socioeconomic groups beginning in toddlerhood (Hoff, 2003).

To date, previous studies have provided limited information about the effectiveness of training on the improvement of young, at-risk children's early vocabulary. Our goal was to examine not only how instructional practices affect at-risk child outcomes but also whether the effects of instruction differentially affect various types of at-risk children. Specifically, our meta-analysis addressed the following questions: 1) To what extent are vocabulary interventions an effective method for at-risk children prior to conventional reading instruction? 2) What factors are associated with significant word learning gains for children at-risk? 3) (How) are various risk populations differentially affected? 4) How do cumulative risk factors affect children's vocabulary gains?

In addition to an electronic database search, we contacted experts in the field for published and unpublished studies. Our searches produced 3,584 relevant papers. Four University graduate students coded a training set of studies (Fleiss' Kappa = .96) and then individually coded the remaining papers; thirty-six met all study inclusion criteria.

Effect sizes were expressed as Hedges' g and weighted by the inverse of their error variances. We examined publication bias using the classic fail-safe N test, which indicated that we would need to be missing 5,538 studies to invalidate our results. None of our effect sizes were outliers.

Our sample comprised 36 individual papers yielding 39 studies and 112 effect sizes resulting in an overall effect size of 0.94, $SE=0.10$ $CI95=0.74, 1.14$, $p<.01$. Our sample was largely heterogeneous thus we conducted moderator analyses to explain variance / examine which factors of instruction were related to child outcomes. We found no significant difference between the gains received by kindergarten ($g=1.13$, $SE=.17$, $CI95=.80, 1.46$) or preschool ($g=.80$, $SE=.13$, $CI95=.56, 1.05$) at-risk children, $Qb(1)=2.46$, $p=.12$.

The figure in Appendix images includes details of all findings. The only significant difference found for type of risk factor was SES. At-risk children with low-SES status ($g=.80$, $SE=.12$ $CI95=.58, 1.03$) received gains that were significantly lower than middle to high SES at-risk children ($g=1.50$, $SE=.25$, $CI95=1.01, 1.98$), $Qb(1)=6.32$, $p=.01$; Middle to high SES children who had at least one risk factor gained more than low-SES children with at least one additional risk factor. Dosage of the intervention on its own was not significantly related to child outcomes and no significant difference was found between interventions given individually ($g=.97$, $SE=.18$, $CI95=.61, 1.33$), in small groups of five or less ($g=.95$, $SE=.18$, $CI95=.61, 1.30$), or in large groups of six or more ($g=1.17$, $SE=.35$, $CI95=.49, 1.86$), $Qb(2)=.32$, $p=.85$. Interventions conducted by child care providers who were non-certified/non-degreed ($g=.23$, $SE=.11$, $CI95=.02, .44$) were significantly less effective than those conducted by parents ($g=.71$, $SE=.26$, $CI95=.21, 1.22$), experimenters ($g=.95$, $SE=.24$, $CI95=.48, 1.42$), or certified teachers ($g=1.25$, $SE=.19$, $CI95=.89, 1.62$), $Qb(3)=25.91$, $p<.001$. Explicitly

taught word learning interventions had significantly higher gains ($g=1.01$, $SE=.16$, $CI95=.71, 1.32$) than implicit / incidental word learning interventions ($g=.57$, $SE=.13$, $CI95=.33, .82$), $Qb(1)=4.78$, $p=.03$. Interventions that combined explicit and implicit instruction ($g=1.52$, $SE=.17$, $CI95=.1.18, 1.85$) were significantly more effective than either explicit alone. Studies whose experimenters specifically selected target words prior to the intervention ($g=1.22$, $SE=.16$, $CI95=.90, 1.54$) had significantly higher effect sizes than those who did not ($g=.73$, $SE=.12$, $CI95=.49, .97$), $Qb(1)=5.80$, $p<.05$. Lastly, interventions assessed with author-created tests ($g=1.37$, $SE=.20$, $CI95=.98, 1.76$) had significantly higher effect sizes than those assessed with standardized measures ($g=.68$, $SE=.11$, $CI95=.46, .91$), $Qb(1)=8.91$, $p=.003$.

Our results provide strong evidence for the overall effectiveness of vocabulary interventions for young, at-risk children. The effect sizes obtained are considered both educationally significant (Lipsey & Wilson, 1993) and large (Cohen, 1988). This is tempered by the fact that 69% of the studies' participants scored at or below the 16th percentile at pretest. Thus, even a large gain may not be enough to narrow the achievement gap for at-risk children. In addition, children living in poverty with at least one other risk factor received the smallest gains and tended to have the lowest baseline scores. In essence, interventions would have to accelerate, rather than merely improve, children's vocabulary development, to narrow the achievement gap. In addition, standardized measures alone may be too obtuse to detect nuanced growth and conceptual changes in vocabulary learning suggesting the addition of more sensitive author-created tests for assessing vocabulary growth in at-risk children.

Our findings suggest that more powerful interventions than have generally been conducted are needed for at-risk children related to the type of intervener, the explicitness of instruction, and whether specific words are targeted prior to the intervention. The study that produced the largest effect size (Coyne et al, 2007; $g=2.13$) provided embedded explicit teaching of words targeted in advance, with 'interactive opportunities..to interact with and discuss target words in varied contexts beyond those offered in the story' (p. 77). This exemplified instruction powerful enough to narrow the achievement gap. Neither the dosage nor the group size of the intervention were related to the magnitude of the child outcome suggesting that policy efforts focus on the quality of instructor and instruction, particularly for the at-risk children in poverty who may have the most limited access. Altogether, our meta-analysis provides some promising recommendations for classroom settings for at-risk children.

PAPER PRESENTATION

Mental representation of diagrams: An investigation using free writing and correspondence analysis

Emmanuel Manalo, Waseda University, Japan; Yuri Uesaka, The University of Tokyo, Japan; Yuichiro Wajima, Tokyo Institute of Technology, Japan; Yoshio Yano, Ishikawa Prefectural University, Japan

The use of diagrams is generally considered to be efficacious in a wide range of settings. However, a number of problems relating to student use of diagrams have been identified in both research and applied educational settings, including inappropriate choice of diagrams to use and lack of spontaneity in use. Previous research findings, that student views and perceptions influence their spontaneity in using diagrams, suggest that understanding how students mentally represent diagrams could help towards understanding and addressing problems about their use. However, the question of how people might normally represent diagrams in their minds had not been previously addressed in research. Thus, the present investigation was an attempt to answer this question. The participants of the study were 129 undergraduate university students in Japan who were asked to free write for 3 minutes on the topic of "diagrams". The free writing data were put through morphological and correspondence analyses, which enabled the proximity between words (nouns, verbs, and adjectives used) to be calculated and plotted on a two-dimensional grid. This plot revealed three main clusters pertaining to words that denote where diagrams are used, words that indicate the functions of diagrams, and words that describe specific kinds of diagrams – with the first two clusters appearing to lie along a possible "depth-of-processing" continuum. The words proximity plot suggests that diagrams may be mentally represented along two dimensions, one pertaining to their entity (i.e., what diagrams are) and the other to their purpose (i.e., what diagrams are for).

Introduction

Diagrams are used in a wide variety of fields (Blackwell & Engelhardt, 2002) and are considered as facilitative of efficiency in computational processes (Larkin & Simon, 1987), including problem solving (e.g., Hembree, 1992; Pedone et al. 2001). Various problems, however, have been identified in their use, including the necessity of prior knowledge for their effective use (Grawemeyer & Cox, 2008) and students' general lack of spontaneity in using them (Dufour-Janvier et al., 1987; Uesaka et al., 2007). Thus, despite their apparent usefulness, many students may fail to benefit from diagrams use.

The majority of studies on diagrams have focused on their effects and functions (e.g., Ainsworth & Th Loizou, 2003; Cheng, 2002, 2003; Mayer, 2003), with very few addressing issues about user problems. One study that falls into the latter category is Uesaka et al. (2007): their key finding was that lack of confidence and perceptions of difficulty in diagram use, and failing to view diagrams as part of their own personal repertoire of learning strategies, were deterrents to students' spontaneous use of diagrams. This finding suggests that understanding how students mentally represent diagrams could be key to understanding and addressing problems about their use.

There is, however, not a lot of research that has been undertaken about how people mentally represent diagrams. Studies have looked at the differences between and effects of active and passive diagrammatic representations (Stern et al., 2003), and the categorizations that people use when asked to sort depictions of different kinds of diagrams (Cox & Grawemeyer, 2003), but the question of how people might normally represent diagrams in their minds had not been addressed. This therefore was the objective of this study.

Method

The participants were 129 undergraduate students (mean age = 19.75 years, SD = 1.57; females = 61, males = 68) in a university for teacher training in Japan. They were administered a questionnaire in three parts. The first part asked them to free write for 3 minutes about "diagrams". The second part sought their opinions about diagrams, and the third part required participants to solve three problems. In this summary, only findings relating to the free writing task will be reported.

Free writing is a technique that has been used to facilitate participants' articulation of their beliefs and ideas about target concepts (see, e.g., free writing uses in Curtis & Millar, 1988; Knobloch-Fedders & Knudson, 2009). Participants' articulations can provide insights into their cognitive structures about target 'objects' (i.e., through the definitions, categorizations, connections, and elaborations they articulate, the structural properties of their cognition can be inferred). The technique was considered appropriate in this study as it reduced the likelihood of making any suggestions to the participants about how they should think about diagrams.

Compared to previous studies that have employed free writing, however, a more systematic, empirical approach was used in this study to analyse the data. First, morphological analysis was undertaken during which the free writing data, which comprised mostly of phrases and sentences, were segmented into words, and then all the nouns, verbs, and adjectives were selected. Frequency counts were made, and only words that occurred 5 times or more were then included. Then, for each participant, the occurrence of these words was identified, hence enabling the co-appearance of words to be worked out. Following this, correspondence analysis, using Hayashi's (1993) quantification methods type III, was conducted. In essence, this enabled the distance between words to be calculated. Finally, the configurations of the words were plotted on a two-dimensional grid to portray the proximity between the words.

Results

The plot revealed three main clusters: (i) words denoting where diagrams are found or are used (e.g., statistics, text books, social sciences), (ii) words that indicate functions, uses, or outcomes of diagrams use (e.g., organisation, understand, imagine), and (iii) words that pertain to specific kinds of diagrams (e.g., graph, line graph, pictures). These clusters were distributed on the grid along what approximated an X-shape without the top left segment. On the top right segment were the first group of words; on the bottom left were the second group of words; and on the bottom right were the third. The top right segment/cluster (location/appearance of diagrams) appeared to lie along a continuum leading toward the bottom left segment/cluster (functions of diagrams).

Discussion

The findings suggest that students mentally represent diagrams in terms of (i) where they know diagrams appear or are used, (ii) the functions or outcomes of diagrams use, or (iii) specific examples or kinds of diagrams. The words proximity plot suggests that the first two may lie along a continuum, from more 'shallow' notions pertaining to where students may have seen diagrams, to more 'deeply' processed ideas about the functions that diagrams use may serve. This continuum connecting the first and second clusters may represent ideas about "what diagrams are for", while the

third cluster may represent ideas about diagrammatic entity (i.e., "what diagrams are"). Hence, it may be that diagrams are mentally represented along two dimensions, one pertaining to their entity and the other to their purpose. Underpinning these dimensions may be the extent to which each student has processed knowledge and experiences about diagrams.

The entity and purpose dimensions suggested by the results of this study require experimental verification, particularly with different groups of students. If these prove to accurately portray how students generally represent diagrams in their minds, they could potentially contribute towards a better understanding of knowledge and skills development about diagrams – and possibly other learning strategies as well. In turn, such understanding could directly help towards the formulation of more effective methods for addressing common student problems in the use of these strategies.

The findings of this study also indicate that correspondence analysis can usefully be employed in applied educational contexts to provide insights into human cognitive structures that may latently be represented in qualitative data such as writing output.

PAPER PRESENTATION

Effects of Headings and Keywording on Learning in Self-regulated Text-based Learning

Marie Lippmann, TU Dresden, Germany; Susanne Narciss, Technische Universität Dresden, Germany; Neil Schwartz, California State University, Chico, United States; Robert Danielson, California State University, Chico, United States; David Sarmiento, California State University, Chico, United States

Metacognitive monitoring affects students' self-regulation, and this affects overall learning. Monitoring accuracy is influenced by the characteristics of the learning material. Thus, this study investigates two common characteristics of text-based learning tasks – headings and post reading summarizing tasks – and their effects on learning processes and outcomes in a self-regulated learning setting. Headings varied in relatedness and distance to the target topics. Summarizing tasks were keyword tasks that took place either immediately (IMM) after reading a text, or with a delay (DEL). In a 2 between, 3 within subjects design, 243 students studied 6 expository texts, generated keywords either immediately or delayed, restudied the texts and performed a posttest with deep-level processing tasks. The results of this study are contrary to former findings indicating a superiority effect on performance for delayed keywording. The results also revealed an interaction of relatedness and distance in the heading conditions – participants in the DEL-condition gave fewer correct answers from text than participants in the IMM-condition if headings were related/close; participants in the IMM-condition gave fewer correct answers from text if headings were related/distant, compared to related/close headings; there was no difference for performance regarding information from text if headings were unrelated. In the unrelated heading condition, performance scores were noticeably high compared to the other heading conditions.

Aims

Self-regulated learning (SRL) is defined as the independently applied monitoring and control of behavior, cognition, or motivation in an academic context (Dinsmore, Alexander & Loughlin, 2008). SRL is affected by monitoring accuracy. Prior research revealed that delayed summarizing tasks increase a learner's monitoring accuracy, which results in better self-regulatory activities and test performance (Thiede, Anderson & Theriault, 2003). Headings are organizational signals (Lorch & Lorch, 1996). Headings have different effects on learning depending on their relatedness to the text content and their distance to the emphasized contents (Richtey, Schuster & Allen, 2008). If headings affect the establishment of a mental text representation, headings may also affect self-regulatory processes. If both, summarizing tasks and headings, affect SRL, they should interact when manipulated in a SRL setting. Therefore, this study aims at investigating the effects of headings and summarizing tasks on learning processes and outcomes in a SRL setting.

Methodology

Participants and design: 243 American students (64 males, 179 females; age range: 18 – 59; mean: 22.7 years) participated in the study. In a 2 between, 3 within subjects design, the between subjects variable was type of summarizing task (immediate (IMM) - delayed (DEL) keywording). The within subjects variable was type of heading (related/close (RC), related/distant (RD), unrelated (UR)). Each participant experienced all heading conditions twice throughout the course of the study. The heading conditions were counterbalanced, following a Latin square. Participants were randomly assigned to the immediate or delayed keyword condition. **Study material, measures and procedure:** The study was run online with 6 expository study texts. Each text consisted of two distinct subtopics of an overall related topic. Topics varied for each text. Each text had 3 different possible heading conditions. In the RC-condition, the heading highlighted the first subtopic in the text. In the RD-condition, the heading highlighted the

second subtopic in the text. In the UR-condition, the heading was not related to any of the subtopics. The presentation of the topics was counterbalanced. Keywords and essays were realized as word documents. The deep-level processing task contained 12 questions with an open answer format. Each of the 12 questions targeted one of the 12 subtopics from the texts. The questions provided a new scenario and a problem statement. The participant was asked to solve the problem and provide an explanation. Correct answers were scored according to a 2-category scoring rubric for two sources of knowledge - knowledge from text (TEXT) and prior knowledge (PK). Answers were scored by 2 different scorers, reaching an interrater reliability of .86. The procedure included learning from texts, keyword generation, comprehension ratings, a first set of reproduction tasks and confidence ratings, a self-regulated restudy trial, a second set of reproduction tasks and confidence ratings, and a deep level processing task (see table 1).

INSERT TABLE 1.

Findings and conclusions

Within the scope of this proposal, only results from the deep-level processing task will be reported. Results were computed using a 2 Keyword (IMM vs. DEL) x 3 Factor Headings (RC vs. RD vs. UR) x 2 Source of Learning (TEXT vs. PK) ANOVA with repeated measures on the factor headings and source of learning conditions. The ANOVA revealed a significant main effect for source of learning [$F(1,241)=511.339$ MSerror=0.557, $p=0.00$] with more information remembered from text ($M = 0.741$; $SD = 0.026$) than from prior knowledge ($M = 0.117$; $SD=0.009$). The 3-way interaction was also significant [$F(1,241)=3.94$, MSerror=0.38, $p=0.04$] (see figure 1). Participants used more information from the texts to answer the questions than information from prior knowledge. Participants with delayed keywording gave significantly fewer correct answers from the text than participants with immediate keywording if the heading was related/close. Participants with immediate keywording gave significantly fewer right answers from the text if the heading was related/distant, compared with the related /close heading. There was no difference for performance regarding information from text between the keyword conditions if the heading was unrelated. Also, the performance level regarding information from text was higher for the unrelated heading condition. When participants brought in information from their prior knowledge to answer the questions, participants with immediate keywording performed significantly better than participants with delayed keywording. Apparently, the keywording and heading conditions affect learning on a number of levels. The RC-condition may cause a perceived ease of comprehension, which has a negative impact on monitoring accuracy, causing an illusion of knowing (Kroll & Ford, 1992). Thus, a lack of deep level processing may occur, which impacts the establishment of a coherent mental model of the text. In the RD-condition, the text structure does not promote a perceived ease of learning and thus, no illusion of knowing occurs. In the UR-condition, the perceived ease of learning is the lowest. Thus, participants are encouraged to apply deeper levels of processing. In some cases, immediate keywording may result in a rehearsal loop that fosters the consolidation of knowledge for simple information, as in the RC-condition (Baddeley, 2003). Significance of findings Headings and summarizing tasks are commonly found in text-based learning tasks. Findings derived from this study contribute to a better understanding of cognitive events and improved design of text-based learning tasks. The paper will address the theoretical issue of self-regulated learning as a mediating variable of comprehension in text-based learning.

PAPER PRESENTATION

Self regulation and sense of community in online learning. An analysis of reciprocal interactions

Barbara Girani De Marco, University of Milano Bicocca, Italy; Ottavia Albanese, universita milano Bicocca, Italy; Stefano Cacciamani, University of Valle d'Aosta, Italy; Giulia Balboni, University of Valle d'Aosta, Italy; Nicoletta Businaro, University of Milano Bicocca, Italy; Stefano Castelli, University of Milano Bicocca, Italy; Alessandra Coscarelli, University of Turin, Italy; Eleonora Farina, University of Milano Bicocca, Italy; Vittore Perrucci, University of Valle d'Aosta, Italy; Luca Vanin, University of Milano Bicocca, Italy; Giovanna Conenna, University of Milano Bicocca, Italy

The development of a sense of community in an online course could increase the level of satisfaction and the academic success (Rovai e Wighting, 2005). Contemporaneously, the participation in a virtual community promotes self-regulation and the reflection on knowledge, motivating the e-learner to assume an active role (Rovai, 2002). In our research we analyze the relationship between the two variables. We hypothesized that more self-regulated students are facilitated to develop an early sense of community. At the same time the early development of the sense of community can offer the optimal conditions for the application in the online courses: that will allow students to enrich their SRL competencies. We asked university e-learners to fill in the Motivated Strategies for Learning Questionnaire (Pintrich et Al, 1993; Italian version by Bordin et Al, 2009) at the very beginning and at the end of the course. A week after the beginning of the course we asked the students to fill in the sense of community in online course scale, developed by Perrucci, Balboni, Cacciamani, (2008). A preliminary sample was composed by 29 e-learners. We analyze correlations between the two variables. Results show an association between early sense of community and incoming SRL, this association increase at the end of the course. The results lead us to verify more in depth the existence of a circular relation between the two constructs with an enlarged sample.

Theoretical framework

The relevance and the variety that distance learning is assuming today, requires a notable effort to plan activities that promote in the students the activation of self-regulative, motivational and relational processes, in order to use effectively the instruments and the contents offered (Albanese, De Marco, Fiorilli, 2008; Perrucci, Cacciamani, Balboni, 2007). The research on the success of the on-line activity meant as an active knowledge building has brought to light the crucial role of two interconnected factors: the self-regulative components of learning and the sense of community among the participants in the lowering of the risk of drop out of the courses, (Rovai, 2002). The theoretical construct of self-regulation is described by Zimmerman (2008) as a group of pro-active self-directive processes and beliefs about self that are used by the student to acquire competences in order to improve personal academic results and to reach fixed goals. Therefore, to evaluate the individual level of self-regulation in learning, it is necessary to consider its multiple components: cognitive, metacognitive, motivational, behavioural and environmental. The concept of "sense of community" is defined, by McMillan and Chavis (1986), as the sense of belonging and hard interdependence of a person within a group, in terms of the perception of being part of a very reliable and stable group, and in terms of being available to offer and to do for the other members whatever one expects from them, and the expectation of seeing one's needs satisfied thanks to the mutual commitment. The online learning at the university is a significant context to study both the sense of community and SRL. Various investigations have revealed that the development of a sense of community in an online course could increase the level of satisfaction and the academic success and could reduce the drop-out (e.g. Rovai e Wighting, 2005). Contemporaneously, the participation in a virtual community promotes an activation of epistemic processes that promote the self-regulation and the reflection on knowledge, enhancing the e-learner's motivation to assume an active role (Rovai, 2002; Albanese, De Marco, Fiorilli, 2008).

Aims and hypotheses

Although the literature shows that blended courses adopting a collaborative and/or co-constructive approach promote the development of self-regulative abilities, assuring at the same time the development and the preservation of an adequate sense of community (Bruckman, 1998), the interrelation between the two variables has not yet been considered and analyzed in depth. In our research we want to identify the relationship between the two variables. We hypothesized that more self-regulated students are facilitated to develop an early sense of community. At the same time the early development of the sense of community can offer the optimal conditions for the application in the online courses: that will allow students to enrich their SRL competencies even more.

Method and data analyses

Participants of our research are university students who attend e-learning courses at Milano Bicocca University. All the courses we take into account in our research are based on collaborative learning or collaborative knowledge building models. A preliminary sample was composed by 29 e-learners. At the beginning and at the end of the online course students were asked to fill in the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich, Smith, Garcia e McKeachie, 1993; Italian version developed by Bordin, Bastianelli e Fluperi, 2009). The questionnaire analyses two different components: the motivational and the strategic one. The motivational scale involves three components (value, expectancy and affect) and the strategic scale involves two components (cognitive and metacognitive strategies and resource management strategies). Each component involves one or more indexes. A week after the beginning of the course we asked the students to fill in another questionnaire, the "Scala del Senso di Comunità nei corsi online" (The sense of community in online course scale), developed by Perrucci, Balboni, Cacciamani, (2008; Perrucci, Cacciamani, Coscarelli, Balboni, 2009) on the model of McMillan e Chavis (1986). Assessing the sense of community after just a week of activity allow us to assess the early sense of community. We correlated the early sense

of community general index with all MSLQ components at the beginning and at the end of the course (non parametric correlation index, Spearman's Rho).

Results

Our preliminary data show significant correlations between three SRL competencies and early sense of community: 1) value ($r=.60$, p Results show an association between early sense of community and incoming SRL competencies. This association increased at the end of the course. The results lead us to verify more in depth the existence of a circular relation between the two constructs (SRL and the sense of community). Our sample will be enriched by 90 or more questionnaires in few months; structural equation models will be used to analyse the new sample to identify causal relations between the two constructs.

Conclusion

Our sample do not allow us to make causal inference from data, but our results suggest the necessity to develop among students inner self regulation competencies and to support the development of the sense of community since the beginning of the course. If further analyses confirm preliminary results, we could suggest the necessity to plan specific activities to allow students to understand the importance of collaboration and sense of community development. The promotion of the sense of community in fact could allow them to get more benefits from the course, not only about discipline's contents, like literature has already showed, but also on transversal competencies like SRL.

PAPER PRESENTATION

A Model Integrating Goal Orientation and Selective Attention Strategy Frameworks

Ordene Edwards, Lamar University, United States

A theoretical model is proposed that would interject the selective attention strategy into an achievement goal orientation framework. The proposed model may explicate one mechanism that underlies the relationship between achievement goal orientation and various learning patterns and outcomes. The basis of the integration of the two learning models is the schema theory which explains the nature of both frameworks. The model focuses on reading and reading comprehension. The model proposes that text salience and attention may mediate the relationship between goal orientations and reading comprehension. The proposed model may expand our understanding of one likely process whereby achievement goals affect learning outcomes.

Purpose

The achievement goal theory evolved as a major research area in achievement motivation (Midgley, Kaplan, Middleton, & Maehr, 1998). Heretofore, a number of researchers have documented the link between achievement goals and learning (see Ames & Archer, 1988; Butler, 1987; Elliott & Dweck, 1988; Elliott & McGregor, 2001). However, a likely reason for the connection is not clearly described in the literature. Thereby, a framework explaining a process by which goals can create and/or sustain engagement or disengagement in learning tasks is warranted.

Education researchers identified and tested other learning models to explain connections among various learning outcomes. These models may also help explain the link between goals and learning. One such model, the Selective Attention Strategy (SAS) conceptualizes one process that may underlie learning, specifically reading comprehension (Reynolds, 1992). SAS research shows that the amount or intensity of students' attention may affect reading comprehension (Goetz, Schallert, Reynolds, & Radin, 1983; Kaakinen, Hyona, & Keenan, 2003). Specifically, they identified positive links among reading variables, attention, and comprehension. Could SAS explain a process whereby goals are related to learning? The objective of this paper is to propose an integrated theoretical model of goal orientation and SAS via the schema theory.

Theoretical Framework and Background

Schema Theory

The schema theory is a relevant framework for connecting selective attention and goal as it is the underlying theory that explains their bases (see Kaplan & Maehr, 2007; Reynolds, 1992). Schema theory helps us understand that learners can effectively use their cognitive capacity to selectively focus on information that are salient to their schemata and ignore information that are non-salient (e.g., Anderson, 1982; Goetz et al., 1983). Schemata set in motion cognitive mechanisms that can affect learning. This essentially describes SAS.

Selective Attention Strategy

According to the SAS, salient information is learned better than non-salient information (Reynolds, Standiford, and Anderson, 1979). That is, individuals allocate extra attention to salient text information, via schema theory (Anderson,

1982), which aids in better learning (Goetz et al., 1983). Can SAS framework help us better understand how goal orientation affects student outcomes?

Goal Orientation

The achievement goal theory emphasizes that individuals construct cognitive representations of motives for academic-related situations (Ames, 1992; Dweck, 1986). Kaplan and Maehr (2007) proposed that situation and self schemas partly explain the nature of achievement goal orientations. That is, goal orientations as cognitive-affective frames can be constructed from schemata that may be tied to specific academic situations (Kaplan & Maehr, 2007). Also, self-schemata inform the individual's expectations and affect all levels of engagement in an academic situation including what they pay attention to, what they can remember, and what they deduce from the situation (Markus, 1983).

A plethora of research shows relationships among goals and learning (Ames & Archer, 1988; Elliott, 1999; Elliot & Church, 1997; Wigfield & Guthrie, 1997). These studies expand our understanding of the relationships among goals and learning. However, they do not answer one important question: how do goal orientations increase/decrease learning? Specifically, do goals influence attention and comprehension of text via the SAS? The proposed model will explore these possibilities.

The Proposed Model

How are goal orientations, text salience, attention, and comprehension related? To answer the question, a model is proposed that integrates goals and SAS via the schema theory. Figure 1 presents the proposed integrated model.

In any reading situation, individuals possess text information schemata and other schemata including achievement goals schemata that influence text salience, attention, and comprehension.

Reading involves a schematic structure for text information (Anderson, Reynolds, Schallert, & Goetz, 1977). An important component of that schema is inference formation that helps readers decide what schema they should activate in order to understand text (Anderson & Pearson, 1984). This schema may influence text salience, which in turn affect attention and subsequently comprehension (Cirilo & Foss, 1980).

Individuals are sometimes given reading perspectives. Instructions and objectives can activate schemata that prompt readers to focus on certain text information (McCrudden & Schraw, 2007).

As individuals read, they use motivational processes (Guthrie & Wigfield, 1999), specifically, goals and beliefs (Pintrich & DeGroot, 1990a). Thereby, self and situation schemata may be activated that guide goal adoption, which in turn influence salience, attention, and learning.

Each type of goal may affect text salience in different ways. These predictions are consistent with the assumptions of Pekrun, Elliott, and Maier (2006) regarding object focus and valence of achievement goals. Individuals with a mastery goal focus on value and controllability of understanding. Therefore, a mastery goal may intensify the salience and value of text as a means to understanding the information. In turn, individuals may devote more attention to reading, which may lead to better comprehension.

On the other hand, a performance approach goal focuses on value and controllability of the outcome of tasks (Pekrun, Elliott, & Maier, 2006). Therefore, a performance approach goal may influence salience solely because of test outcomes. Consequently, individuals may spend less time understanding information (see Wigfield & Guthrie, 1997) and adopt strategies that aim to demonstrate their ability rather than increase competence (Midley et al., 2001). For example, they may focus only on information they believe may appear on the test. This may lead to good grades but not necessarily good understanding (see Midgley et al., 2001). Moreover, their attention may be less than that of mastery oriented readers.

Individuals with a performance avoidance goal focus on failure, the negative value of the task outcomes, and lack of controllability (Pekrun et al., 2006). This may evoke text salience tied to test outcomes, anxiety, and fear, which may decrease attention.

The model also presents the possibility of goals directly affecting salience. Given that schemata can be implanted into each other (Anderson & Pearson, 1984), it is possible that goal schemata may activate certain text information schemata that match specific goals, which may influence salience. For example, a mastery goal may prompt focus on text just to master information, which may be the entire text. Performance goals may prompt focus on information

that may help with getting a good grade (performance approach) or decrease focus on text information because of fear (performance avoidance).

Significance

This model may be the first step in establishing a useful parallel between selective attention and motivation. It may also allow for more grounded and warranted theoretical connections among goals and learning. That is, it may identify one causal mechanism whereby achievement goal orientations are linked to academic outcomes.

PAPER PRESENTATION

Enhancing self-regulated learning with texts: Towards self-paced monitoring

Christian Stamov Roßnagel, Jacobs University Bremen, Germany

The self-monitoring approach posits that improving the metacognitive monitoring of learning enhances learning performance (Dunlosky et al., 2005). With three experiments, I sought to contribute to an applied self-monitoring approach. In the first experiment, I tested whether manipulating the monitoring criterion boosts accuracy by comparing local and global matched and standard judgements of learning, respectively. Accuracy exceeded .82 when participants locally (after each text segment) judged the likelihood of correct answers in a knowledge test compared to judging the likelihood of keyword recall. In the second experiment, I manipulated the sequence of easy and difficult segments as measured by propositional density. Participants read different difficulty sequences (e.g., EDEDED, DDDEEE) and made global or local matched JOL. The latter type of JOL covaried with the difficulty sequence and yielded superior accuracy to global JOL, showing how judgements can be systematically biased. In the third experiment, participants made an ease of processing (EoP) judgement after each text segment and were instructed to make a matched JOL after the EOP rating only if they had made a low EoP rating. Control group participants after each segment made both JOL and EoP judgements. As a main result, participants in the experimental group performed significantly better in the knowledge test than control participants. Moreover, metacomprehension in the experimental group was .91, as compared to .63 in the control group. We discuss how such self-paced ("spontaneous") monitoring may be used to design self-regulated learning trainings.

The self-monitoring approach of text learning posits that improving the metacognitive monitoring of learning enhances performance (Dunlosky et al., 2005). Self-monitoring appears to work with complex settings and materials, such as academic lectures (Nietfeld, Cao, & Osborne, 2005), chess problem-solving (De Bruin, Rikers, & Schmidt, 2007), and with texts containing diagrams (Serra & Dunlosky, in press). Given the importance of meta-cognitive control for real-world learning (e.g., informal workplace learning, see Schulz & Stamov Roßnagel, 2010), the self-monitoring approach may be a promising platform for developing self-regulated learning trainings.

Three issues need dealing with, however, on the way to an applied self-monitoring approach. First, self-monitoring significantly predicts learning performance, but monitoring accuracy is often low (Dunlosky & Lipko, 2007). Second, accuracy is affected by features of the materials such as test question difficulty (Nietfeld, Cao, & Osborne, 2005) or presentation format (e.g., Serra & Dunlosky, in press). Third, participants use self-monitoring strategies when prompted, but little is known about spontaneous, self-paced monitoring.

In three experiments, I therefore tested whether judgement accuracy depends on the self-monitoring criterion (Exp. I), how context effects bias learning judgements (Exp. II), and whether two-step judgements of learning support self-paced monitoring. In Exp. I, 80 participants read expository texts and took a knowledge test. Texts were divided into segments of 2-3 sentences each; segments were requested by keypress. In a 2x2 design, half the participants made judgements of learning (JOL) after each segment (local monitoring) or after reading the entire text (global monitoring). Half the participants in each monitoring condition either judged the likelihood of recalling the keyword (standard JOL) or of answering a test question (matched JOL). Local JOL yielded higher accuracy than global ones; this local effect was most pronounced for matched JOL.

In the second experiment, I manipulated the sequence of easy and difficult segments as measured by propositional density. 40 new participants read different difficulty sequences (e.g., EDEDED, DDDEEE) and made global or local matched JOL. The latter type of JOL covaried with the difficulty sequence and yielded superior accuracy to global JOL, showing how judgements can be systematically biased.

In the third experiment, 40 new participants read the texts used in Experiment II. In the experimental group, participants made an ease of processing (EoP) judgement after each segment, stating how comprehensible they found the segment. In addition, participants were instructed to make a matched JOL after the EOP rating only if they had made a low EoP rating. Control group participants after each segment made both JOL and EoP judgements. As a main

result, participants in the experimental group performed significantly better in the knowledge test than control participants. Moreover, metacomprehension in the experimental group was .91, as compared to .63 in the control group. We discuss how such self-paced ("spontaneous") monitoring may be used to design self-regulated learning trainings.

PAPER PRESENTATION

Validation of CIE-TMa: an instrument of measure of the emotional impact of mathematics learning

Rosario Del Rey, Seville University, Spain; Esther Madera, Cordoba University, Spain; Rosario Ortega-Ruiz, Universidad de Cordoba, Spain

The area of Mathematics is one of the most linked to the school failure (Bermejo, Lago, Rodríguez and Péêrez, 2000) and there are a lot of students who relate it with inappropriate attitudes and especially with emotional shocks and refuse to this kind of learning (Gómez-Chacôn, 2000). In this paper we present the design and validation of the questionnaire CIE-TMa (Cuestionario sobre Impacto Emocional y Tareas Matemáticas – Emotional impact and mathematics tasks questionnaire), whose aim is to highlight the emotional impact (resilience versus mental block) to which Secondary students face when they tackle tasks of mathematic learning. The data obtained from the initial pilot questionnaire was used as a base for the CIE-TMa elaboration, which finally has been validated by a sample of 342 participants. The results indicate that the CIE-TMa possesses enough psychometrical properties and it can be used to measure the three factors which can influence in the success perception to the mathematic tasks in an adequate way: self-confidence, resilience capacity against the perception of failure and emotional block.

Introduction

In the last few years, with the aim of measuring the students' achievement, several public organisms have carried out certain studies which have ranked and classified the different countries on the basis of the level of development of the basic competencies. The most utilized as a reference for comparing the learning quality is the Programme for International Student Assessment, PISA (2000; 2003; 2006), set up in 1997 by the OECD for measuring the level of development of some basic competencies in which the capability of dealing with mathematics is included.

When developing these competencies thorough learning tasks, and in particular the mathematics competency, the attitude and interest of the students occupy an important position according to the experience of teachers of this area (Gil, Rico y Fernández, 2002). The concept that the students have about themselves as trainees in mathematics appears to be one of the variables that has influence on the self-confidence when facing the task. Such a variable has an essential role at the time of achieving positive academic results (McLeod, 1992). But, particularly, the emotional modulation what each student do during the learning process which is specially linked with the academic self-esteem. Claxton (1999) stated the need for the trainees to maintain for learning an adequate level of confidence and, with the goal of explaining the emotional participation in the learning process, established a cognitive-behavioral model which considers that emotions may play a stimulating and positive role or, on the contrary, turn into barriers for achieving an effective learning. For such purpose, we use the personal tools that he classified in three great groups: reflection, resources and resilience.

The purpose of our study has been the implementation of resilience micro procedures against the mental block when tackling the school task of learning mathematics, the designing and validation of an instrument for detecting the emotional impact that said tasks have on the students, considering the influence in the impact of the self-confidence of the students, the resilience capacity and the emotional block that is provoked.

Methodology

On the basis of the theories stated by Claxton (1999), we elaborated a 20 items questionnaire ". The initial hypothesis was to consider the existence of a factorial and empiric relationship that supports the virtuality of the referred theories in relation to the mathematic learning. Once the instrument was designed, we developed a pilot study with a sample of 95 students among six groups of Second Grade of ESO (14 year-old). A factorial analysis was performed with data obtained, which showed the existence of three factors but also some series of items which were not correlated to any of them. After eliminating and reordering the items, the definitive version of the CIE-TMa Questionnaire (Emotional impact and mathematics tasks questionnaire, Madera, Ortega y Del Rey, 2009), composed of 13 items, was elaborated. The questionnaire was answered by 342 students of ESO following the standards of voluntarily, anonymity and independence.

Results

When performing the factorial analysis we checked that, in effect, the use of this analysis was feasible (Bartlett Sphericity Test =1161.095; $p=.000$). The KMO coefficient of Kaiser-Meyer-Olkin offered a value of .811. The variation percentage was of 55.66% and the Cronbach α for each of the three resulting factors: .833 for block, .636 for resilience and .668 for self-confidence. In the oral presentation the items composing all of them will be described.

Conclusions

The exploratory study suggests that the emotional modulation that students do when facing mathematic tasks may be regarded as tridimensional. The exploratory factorial analysis showed that a structure of three factors (self-confidence, resilience and mental block) is adequate, explaining an acceptable total variation percentage for measuring emotional impact and the way to deal with it when tackling school tasks related to the learning of mathematics. In addition, the scale has a good internal consistence.

The results of this study indicate that the CIE-TMa has good psychometric properties, contrasted by the KMO coefficient and the Cronbach α . Therefore, it provides us with an acceptable measure of the different factors that have influence when facing said tasks. In addition, it shows a good performance with the sample of students utilized, which increase the possibilities for its utilization with more representative samples.

On the other hand, given its simplicity and ease to be used by the teachers of mathematics and by other educational agents as school counselors, the CIE-TMa seems to be an useful instrument that may, in case used as a diagnosis instrument, anticipate and prevent many of those little and big problems related to motivation and attitudes towards learning one of the most relevant school domains: the mathematics competency.

PAPER PRESENTATION

The Relation between Situational and Individual Interest and the Quality of Instruction in Mathematics

Ariane S. Willems, TU Munich, Germany

The paper focuses on the analysis of students' interests in mathematics. Based on results that document a motivational decrease during students' school careers, it appears vital to identify contextual factors that facilitate interest development. Here, the theoretical framework of a situational interest is employed. This construct focuses on a two-phase process of externally triggering interests in particular learning situations and maintaining interests over

time. Comprehensive research results based on theories on learning motivation and theories on learning and instruction suggest that the instructional quality of classroom processes is a significant influencing factor for both triggering and maintaining interests. Theories on interest development complementary emphasize the association between a situational interest of students and a manifested subject-specific interest. As empirical evidence on the interrelation of the situational interest, the subject-specific interest, and the quality of instruction in math is currently lacking, the paper aims at disentangling the interaction of these constructs. It is investigated if the subject-specific interest moderates the influence of the quality of instruction on the two SI-phases. Using data from a questionnaire study (N=951 students; N=38 classes), cross-level interaction analyses applying HLM were performed. The results revealed that the situational and the subject-specific interest are related, but separate constructs. Both SI-phases are significantly predicted by different aspects of the quality of instruction. The strengths of these interrelations are mainly independent from the level of the students' manifested subject-specific interests.

Research results on the facilitation of students' learning motivation and interest in mathematics show that both, the learning motivation and the students' interest in math are relatively low and decrease over time (German PISA-Consortium, 2004; OECD, 2004; Rakoczy et al., 2007; Stigler et al., 1999; Kßller, Baumert & Schnabel, 2001). Although the causes for this situation are complex, empirical analyses recurrently document that the quality of instruction plays a vital role in explaining motivational processes across different subject areas (Rakoczy et al., 2007; German PISA-Consortium, 2004). Studies based on theories on learning and instruction primarily investigate a general, comprehensive quality of instructional processes which are measured by the students' retrospective perception of a typical (math) lesson. Such an approach sheds light on general trends in the development of students' learning motivation and interests. In particular, studies document that the perceived lesson structure, goal clarity, and cognitive activation are important variables that predict the quality of motivational processes (German PISA-Consortium, 2004; Kunter, Baumert & Kßller, 2007; Rakoczy et al., 2007). However, these macro-genetic assessments do not account for situation-specific aspects of instruction and are therefore insufficient to describe processes in the development of motivation/interest. Such shortcomings are addressed in current theories of interest development which explicitly distinguish between a situational and individual interest (SI/II). According to these theories, a SI is a content related motivational quality which emerges in response to specific features of a particular learning situation. (Hidi & Renninger, 2006; Krapp, 2002; Linnenbrink-Garcia et al., 2010; Schiefele, 2009). As such, SI is understood as a state-variable that mainly operates within specific learning situations. Conceptually, two developmental SI-phases are distinguished: Triggered and maintained situational interest (SI-Catch/SI-Hold; Hidi & Renninger, 2006; Mitchell, 1993). A triggered SI mainly involves heightening the affective experiences individuals associate with the learning environment; a maintained SI is a more involved, deeper form of the situational interest in which individuals begin to forge a meaningful connection with the learning content and start to realize its deeper significance. From an educational viewpoint, the SI-concept is important because it provides a description of how interests develop and may carry over from one learning situation to another.

Additionally, this framework suggests ways in which teachers can contribute to the development of their students' interests by identifying situational factors of a learning environment that help to trigger and maintain interests. In contrast to a relatively short-lasting SI, the individual interest of students is conceptualized as a trait-variable that has a dispositional quality and resides in individuals across situations (Krapp, 2002). In school contexts such as mathematics instruction, individual interests are usually manifested in stable subject-specific interests. From an ontogenetic perspective, triggering and maintaining interests in a particular learning situation facilitates the development of individual interests (Hidi & Renninger, 2006). Against this background, theoretical frameworks of interest development additionally emphasize the complex interdependence between the SI of students and their subject-specific interest: Following these considerations, states of interest in specific learning situations arise through an interaction between the person and the context (Krapp, 2002). Therefore both situational and individual factors should be taken into account when analyzing different levels of interest in specific learning situations. Following the Four-Phase-Model of Interest Development, first stages of interest should be more closely related to contextual factors and less to individual factors. This pattern should gradually change during the course of interest development, so that later stages of interest development should be less directly affected by contextual factors and more closely related to individual factors (Hidi & Renninger, 2006).

Generally, there is only little research on how contextual factors can promote interest in a particular learning situation. Furthermore, no empirical evidence exists that helps to disentangle the relationship between SI, subject-specific interest and the students' perception of the quality of instruction. One reason for this situation may be that the field currently lacks a valid and reliable tool for measuring SI. Such an instrument does not only need to differentiate between both SI-phases. Furthermore, the measurement scales used for assessing SI should be empirically distinguishable from a subject-specific, individual interest. In line with these considerations, the goals of this paper are (a) to introduce a measurement scale for the assessment of the SI, (b) to clarify the relationship

between the perceived quality of instruction and both SI-phases, and (c) to investigate the role of a subject-specific interest for the state of interest in particular learning situations. To approach these goals, a questionnaire study (951 8th grade students from 38 classes) was conducted. The students were surveyed immediately after a math lesson dealing with the topic linear functions. The questionnaire included newly developed scales for the assessment of SI-Catch and SI-Hold and scales for measuring the subject-specific interest and the quality of instruction. Cross-level interaction analyses were performed in which both SI-phases served as dependent variables on the individual student level, the three aspects of the quality of instruction as independent variables on the class level and finally, the subject-specific interest as (cross-level) moderator on the individual student level.

The results show that the two SI-phases can be empirically separated from each other and need to be distinguished from a subject-specific interest. As expected, all three interest constructs are positively correlated. The results obtained via HLM illustrate that a higher overall predictive power of the quality of instruction can be found for SI-Catch. When controlling for the individual interest, the predictive power of the quality of instruction for both SI-Catch and SI-Hold is only slightly reduced. The cross-level interaction analyses revealed that the strength of the relationship between the perceived quality of instruction and the situational interest is independent from the level of the subject-specific interest. Only one exception was found: The effect of the perceived goal clarity on SI-Catch is higher for students with high subject-specific interests. Although SI and II are highly associated, these results emphasize that contextual factors can trigger and maintain SI in math mostly independent from the individual interest level.

PAPER PRESENTATION

Cognitive, social and affective factors related to engagement in instrumental music learning

Jennifer StGeorge, University of Newcastle, Australia; Allyson Holbrook, SORTI, The University of Newcastle, Australia

The power of music to shape personal living and lifelong trajectories has been long acknowledged, but the experiences that contribute to successful and enjoyable participation in musical instrument learning have been less clearly identified. Drawing on mixed methods research that explored engagement with learning, I show how the nature and quality of the learning experience influenced continuing involvement with music for a group of children, youth and adults in Australia. I set out an explanation for continuation that consists of a set of interrelated experiential domains. When experiences in each of these domains of experience were satisfying, there was a greater likelihood for research participants to continue their involvement with music. This research provides a way of understanding how and why music students become attached to their learning and can continue to be so, illustrating the importance of considering both the individual and their context. The practical implications suggest that educators will be in a better position to foster musical meaning and affinity if they target students' practice approaches while closely appraising the social context of student learning.

Theoretical background and research question The power of music to shape personal living and lifelong trajectories has been long acknowledged, but the experiences that contribute to successful and enjoyable participation in musical instrument learning have been less clearly identified. Most individuals have to work hard to succeed at learning a musical instrument simply because playing an instrument fluently is not easy. For any instrumental music student, the demands of skill building are high: regular and accumulated practice, effective practice routines, self-evaluation and emotional perseverance (Hallam, 1997). However, to remain involved, the experience should be engaging mentally and emotionally in order for the child to effectively process and assimilate the required array of complex skills. Boredom and disinterest occur when these emotions and cognitions are not engaged (Damrad-Frye & Laird, 1989; Ryan & Deci, 2000b). The prevalence of boredom in studies of attrition from music (AMA, 2001; Bushong, 2005; Govel, 2004; Klinedinst, 1989; Pitts et al., 2000b; O'Neill, 2001) suggests that the mental, emotional, or subjective experience of learning is a significant determinant of children's decisions to continue. The aim of this study was therefore to investigate the subjective nature of the learning experience in childhood and youth, and to understand how these varied subjective experiences influence intention to continue learning an instrument. This paper summarises the findings from the final stage of a three part analysis.

Methods

In the research reported here, a mixed methods design with quantitative and qualitative methods as complementary strategies was used in order to explore overlapping but different facets of the phenomenon of music learning and its relationship with continuing participation (Greene, Caracelli & Graham, 1989). The first stage of the study consisted of a questionnaire administered to primary and secondary school students across eight schools (n=376). The questionnaire was administered to complete year-groups of students (Years 5 & 6, and 10 & 11) who were either currently learning a musical instrument, had discontinued formal instruction sometime in the past, or had never learned an instrument. In the second stage, group and individual interviews (n=66) were held with individuals who had learned an instrument during childhood and/or youth (primary school students, tertiary students and adults in the

community), and into young adulthood (tertiary students). The first stage employed descriptive and inferential analyses, while the qualitative method consisted of a bricolage of thematic and phenomenological analysis (Larkin, Watts & Clifton, 2006). The first stage laid the foundation for the major status qualitative method by establishing the dimensions of music learning most relevant to continuing participation, while in the second stage, the contexts and processes that underlay these dimensions were explained through an interpretive account of participants' experiences.

Overall findings

Through the synthesis of the two stages of analysis, an account was developed to explain the relationship between students' learning experiences and their decisions to continue learning. Participants' interactions across five interrelated domains determined how they developed, sustained or lost their connection to learning an instrument. The first, affinity for music, represented a connection with music; it constituted the degree of significance, value or meaningfulness held in music by the individual and was characterised by varying intensities of positive affective states. Affinity for music developed where learning was musically meaningful and where affective responses to learning and to music were predominantly stable and positive. Contributing to musically meaningful experiences were experiences in two further domains; the cognitive, which included participants' understanding of their learning and their levels of instrumental fluency, and the social, which involved the immersion of the student in repertoire that had resonance with their cultural context, that is, their families, their friends, and their learning environment. Figure 1 shows the relationships between each of these domains.

Discussion and conclusion

An understanding of the role affect plays in learning has been an important research agenda of recent times (Ainley, 2006; Isen & Reeve, 2005; Linnenbrink & Pintrich, 2002), although its role in instrumental music learning has been generally overlooked. This research explains that, as a connecting agent between the individual and the activity, affinity for music facilitates the learning of music. Having a high affinity for music was generally associated with continuing involvement, although this involvement varied across listening and making music. Affinity for music was both an outcome of consistent, positive involvement with music playing and learning, as well as a motivator for continuing. The notion of affinity comes closest to the concept of interest as discussed by Hidi and Renninger (2006). An important difference between their four-phase interest model and the phenomenon of affinity proposed here may be the power of affinity to be a potent, internalising influence that is not only gauged by positive affect, but more powerfully blossoms as self-identity, in this study, as a 'musician'. The concept of affinity provides a way of understanding how and why music students become attached to their learning and continue to be so, illustrating the importance of considering both the individual and their context (Beltman & Volet, 2008; Buckley et al., 2004; Evans, 2009). The account developed here points to ways in which teachers might explore the complex interrelationships between subjective, aesthetic, or emotional experiences and objective skill development in music performance education.

PAPER PRESENTATION

The impact of school support at home on students' educational aspirations and attitudes

Louise Elffers, University of Amsterdam, Netherlands

Positive educational attitudes are critical for school success. However, the strength of this relationship differs between sociodemographic groups. Various studies point at the important role of support for school in students' home environment for their educational attitudes and achievement. We conducted a study with a sample of 1438 first-year students upon entrance to post-secondary vocational education in the Netherlands. Using multilevel regression analyses, we assessed the influence of support for school in students' home environment on their educational aspirations and attitudes. Moreover, we examined differences in the amount of support, and in aspirations and attitudes, between various sociodemographic groups. Results indicate that support for school, in particular from parents and peers, has significant impact on students' educational attitudes and aspirations. Immigrant students report significantly higher aspirations and more positive general attitudes towards education. While limited support may explain why immigrant students often appear less successful in transforming their positive attitudes and aspirations into school success, our findings do not correspond with such an explanation. Some sociodemographic groups that are overrepresented in Dutch dropout statistics report lower levels of support in their home environment, which may play a role in this overrepresentation. Implications of our results for educational research and practice are discussed.

Introduction

Educational attitudes and aspirations are positively related to academic achievement. However, the strength of this relationship differs between sociodemographic groups. Various studies point at the important role of support for

school in students' home environment for their educational attitudes and achievement. Limited support at home may restrain students from succeeding in school despite positive attitudes. In this paper, we assess the influence of support for school in students' home environment on their educational aspirations and attitudes. Moreover, we examine differences in the amount of support, and in aspirations and attitudes, between various sociodemographic groups.

Theoretical framework

Positive educational attitudes are critical for school success. If students have high aspirations and positive attitudes towards their education, they are more likely to succeed (e.g. Ekstrom et al. 1986; Maehr and Meyer 1997; Morgan 2005; Sewell and Shah 1968; Tinto 1993). However, while students with a lower socioeconomic or immigrant background generally report more positive aspirations and attitudes, those aspirations and attitudes do not seem to contribute to their school success as much as for middle class and non-migrant students (Alexander, Entwisle and Bedinger 1994; Downey, Ainsworth and Qian 2009; Kao and Tienda 1998; Mickelson 1990; Van der Veen and Peetsma 2006). The expectations that significant others hold of the student may play a mediating role in the relationship between sociodemographic background and educational attainment (Davies and Kandel 1981; Sewell and Shah 1968). The interpersonal influence of significant others on students' aspirations and expectations is a prominent notion in motivational research as well (Wigfield, Eccles and Rodriguez 1998). In particular, the importance of parents' emotional and practical support for school has been established in various studies (Alexander, Entwisle and Kabbani 2001; Ekstrom et al. 1986; Hossler and Stage 1992; Linnenbrink-Garcia and Fredricks 2008; McCarron and Inkelas 2006; McMillan and Reed 1994; Rumberger 1995; Schoon 2008; Trusty 1998). Peer behavior and attitudes have been shown to impact students' educational attitudes as well (Chang and Le 2005; Ryan 2000; Steinberg, Dornbusch and Brown 1992). Students make use of supportive ties from various networks for their school careers (Crul 2000; Stevens et al. 2009). For many working class and minority youth, the supportive ties that are particularly useful for their school career may be found mainly outside the family, for instance among other relatives or friends (Stanton-Salazar and Dornbusch 1995; Stevens et al. 2009).

Method

We conducted a study with a sample of 1438 first year students upon entrance to post-secondary vocational education in the Netherlands. The following variables were measured with a self-report questionnaire:

- . Sociodemographic characteristics: gender, age, ethnic background, socioeconomic status (parents' job status, educational level parents, financial circumstances)
- . Support for school: parents ($\alpha=.67$), peers ($\alpha=.68$), community in general ($\alpha=.73$).
- . Educational aspirations ($\alpha=.74$), general attitudes towards education ($\alpha=.80$).

We performed multi-level regression analyses with class ($N=61$) and students ($n=1438$) as two levels.

Preliminary results

1. Impact support on educational attitudes

The amount of support has a significant impact on students' aspirations and educational attitudes. Support from parents has most impact on students' aspirations ($b=.18$, $p=.021$, p

2. Differences in support

Boys ($b= -.12$, $p=.033$, $p=.028$, $p=.036$, $p=.040$, $p=.041$, $p=.016$, $p=.023$, $p=.026$, $p=.026$, $p=.039$, $p=.018$, p

3. Differences in educational attitudes and aspirations

Immigrant students report significantly higher aspirations (Surinamese students $b=.40$ $p=.027$ $p=.040$ $p=.030$ $p=.039$ $p=.056$, $p=.038$, $p=.011$, $p=.006$ $p=.012$, $p=.019$, p

Discussion

Our results attest to the importance of support for school in students' home environment for their educational aspirations and attitudes. Boys, some immigrant groups, students with low educated parents and students from poor families report lower levels of support from parents, and/or from peers and their community in general. Those groups are overrepresented in Dutch dropout statistics (Dutch Ministry of Education Culture and Science 2009). It is possible that lower levels of support for school play a role in this overrepresentation. Immigrant students report higher aspirations and more positive attitudes. While limited support may explain why immigrant students often appear less successful in transforming their positive attitudes and aspirations into school success, our findings do not correspond with such an explanation. The immigrant groups who score significantly higher on aspirations and attitudes, do not score significantly lower on support, with the exception of students from other ethnic backgrounds than native Dutch/Moroccan/Turkish/Surinamese/Antillean. A longitudinal follow-up study will enable us to assess the impact of

students' aspirations, attitudes and support on their achievement. We hope to present results from this follow-up study at the Earli 2011 conference as well.

Our findings stress the value of a broad perspective, taking into account both the home and school context, in research on motivational processes and academic achievement. Moreover, our findings underline the necessity to compensate limited supportive resources in students' lives, as those resources have significant impact on their orientation towards school. Schools and community organizations can offer personal coaching and support, with the help of mentors at school, external coaches, or peer tutoring programs, to ensure adequate access to resources to support successful school careers for all.

PAPER PRESENTATION

The effectiveness of one-to-one private tuition in England

Katie Rushforth, Institute of Education-London, United Kingdom; Judith Ireson, Institute of Education-London, United Kingdom

Amidst reports that the private tuition industry is rapidly expanding and government pledges to fund one-to-one tuition for a substantial number of students in England, this paper examines the impact of private tuition on attainment. Research shows that tutoring programmes can be very effective in raising achievement, yet some studies have found negligible learning gains. This paper presents findings on the impact of one-to-one private tuition in maths and English on Key Stage 2 (KS2) and General Certificate of Secondary Education (GCSE) achievement. Data on private tuition participation was collected from over 2000 pupils aged 10-11 and 15-16 years from 30 primary and 28 secondary schools in England, and was matched with centrally collected government data on achievement. Using statistical modelling that reflects school effects in the data and controlling for prior attainment and pupil background characteristics, private tuition in maths was found to have a significant impact on maths achievement at GCSE. There was no evidence to suggest that private tuition in English made an impact on respective GCSE or KS2 attainment. Using a combined measure of tuition in any subject, findings indicated that extended periods of private tuition made a small impact on maths KS2 and GCSE achievement. These findings suggest that one-to-one tuition in mathematics may give students an advantage in the education system but that tuition in English may be less effective. Reasons for these differences are discussed.

Aims

International surveys indicate wide variation in the extent of private tutoring (Baker, Akiba, LeTendre, & Wiseman, 2001). A recent survey of parents in England found that 12% of primary and 8% of secondary school pupils participate in private tuition (PT) (Peters, Carpenter, Edwards, & Coleman, 2009). The "Mapping and Evaluating Shadow Education" (MESE) project found 27% of pupils had participated in PT at some point during their schooling (Ireson & Rushforth, 2009). These findings suggest that a large proportion of parents consider PT a worthwhile investment, perceiving a link between educational achievement and future career progression. Despite the numbers of students participating in PT, research in this field is largely absent from the education literature. Amidst reports that the PT industry is rapidly expanding and government pledges to fund one-to-one tuition for a substantial number of students in England, this paper aims to investigate the impact of PT on attainment at two transition points in the education system; the end of Key Stage 2 (KS2) when students are aged 10-11 (year 6) and the end of Key Stage 4 (KS4) when students take their GCSE examinations aged 15-16 years (year 11). Ellson (1976) states that "there is a widespread belief among educators and laymen that individualised instruction, especially in a one-to-one teaching situation, is almost infallibly effective" (p. 133). Logically one could conclude that spending time engaged in supplementary learning activities would increase achievement; however as a number of studies have shown this does not always convert into higher test results (Baker et al., 2001; Ireson & Rushforth, 2005; Smyth, 2008, 2009).

Methodology

The data analysed for this paper was collected as part of the MESE project which employed a stratified sampling strategy through the distribution of questionnaires in schools selected to represent a range of demographic areas. The sample included schools from Local Authorities (LAs) across central and southern England with a range of ethnic diversity and social disadvantage, from a cross-section of urban, suburban and rural areas including both selective and comprehensive schooling systems. In total 30 primary and 28 secondary schools were involved in the study from 10 LAs. This provided questionnaire responses from a total of 2468 pupils. KS2 and GCSE attainment and pupil background data supplied by the Department for Children, Schools and Families was utilised to determine the impact of PT on attainment. Statistical modelling was completed using fixed effects robust regression models to give less weight to outlying cases and to ensure transparency during data analysis (Beaton & Tukey, 1974; Huber, 1964; StataCorp, 2009). To reduce the risk of making inaccurate inferences in the presence of heteroskedacity, the robust estimate of variance (Huber, 1967; White, 1980) was also calculated. To explore the impact of PT on achievement,

separate models were constructed for year 6 and year 11, using KS2 tests and GCSE examination results as the dependent variables. The models controlled for prior achievement, gender, home possessions, time spent on homework, extra classes, gender and ethnicity. Three different measures of PT were added to the models to indicate participation in English and maths tuition and a combined measure of PT in any subject. For each year group variables were included to reflect the intensity of PT participation (one term or two or more terms).

Summary of main findings

The analysis revealed that PT in maths and the combined measure of PT in any subject had significant effects on maths GCSE scores. The overall effect of two or more terms tuition in maths during the two years prior to taking the GCSE examinations represented an effect size (ES) of 0.25 (nearly half a GCSE grade). No evidence was found to suggest that PT in English made an impact on respective GCSE or KS2 achievement, although the combined measure of PT in any subject had a significant effect on English score in the GCSE analysis. A significant effect was found for extended periods of PT in any subject on KS2 maths score (ES 0.24). An analysis of the interactions between PT and other explanatory variables indicated that the effect for PT was greater for certain groups of students and in certain subject areas; however, the interactions were based on very few participants and should be treated with caution.

Significance of the research

This paper presents, for the first time, a systematic and rigorous analysis of the effects of PT on student attainment at two key transition points in the English education system. It employs an innovative methodology that combines data collected centrally by government with data from questionnaires completed by students. The findings extend an earlier analysis of a subset of data (Ireson & Rushforth, 2005) and indicate that intensity is an important variable to include in future research. In 2007, the government outlined plans to provide progression tuition by qualified teachers for students who are not making expected levels of progress. Progress tuition comprises an "intensive burst [10 hours] of individual tuition" in English and/or maths for a number of pupils aged between 7 and 14 years (KS2 and KS3) (Department for Education and Skills, 2007, p. 23). An evaluation of progression tuition in the pilot phase found a small significant effect on progress in reading and writing but no significant impact in maths (Pricewaterhouse Coopers LLP, 2010). In April 2009 the government provided funding directly to all LAs to allow 3.5% of KS2 and KS3 pupils to access one-to-one tuition. The provision of progression tuition in the state sector is likely to have an impact on PT providers and the demand for PT in England (Rushforth, 2010).

PAPER PRESENTATION

The family-study interface and academic outcomes: Testing a structural model

Marieke Meeuwisse, Erasmus University Rotterdam, Netherlands; Marise Ph. Born, Erasmus University Rotterdam, Netherlands; Sabine Severiens, Erasmus University Rotterdam, Netherlands

Expanding on family-work and work-study models, this paper investigated a model for family-study conflict and facilitation. The proposed model extended prior research by explicitly distinguishing between time-based, strain-based and behavior-based conflict, and instrumental and affective facilitation. The focus of the study was the relationship between these types of family-study conflict and family-study facilitation and students' effortful behaviors, school satisfaction and academic performance among a sample of university students (N = 1656). Model tests using structural equation modeling identified participation in family activities, family social support and involvement with family as antecedents of both family-study conflict and family-study facilitation. In turn, family-study conflict was negatively related to study effort and school satisfaction, and family-study facilitation positively contributed to students' study effort and school satisfaction. Both effort and school satisfaction positively predicted students' GPA.

School is an important realm of students' lives. However, student jobs have become a major activity as well (Butler, 2007; Derous & Ryan, 2008). Besides work, students also spend time with their families and are involved in leisure activities (e.g., spending time with friends, sports). As a consequence, students need to combine their role as a student with their roles as an employee, family member and friend. Combining multiple roles can result in conflict between (Ford, Heinen & Langkamer, 2007; Greenhaus & Beutell, 1985) as well as facilitate (Greenhaus and Powell, 2006; Wayne, Grzywacz, Carlson & Kacmar, 2007) these roles. Although most research has focused on the work-family interface, several recent studies suggested similar conflicts and facilitation between work and school (Butler; Markel & Frone, 1998). As Herndon and Hirt (2004) argue that the family is important for educational attainment, the present study investigates to what extent possible experienced family-to-study conflict and family-to-study facilitation relate to the school performance and school satisfaction of students.

The participants are 1656 fulltime university students at a four year university in the Netherlands. Each participant completed an online version of a questionnaire measuring conflict and facilitation between the family domain and the

study domain, possible antecedents of conflict and facilitation, and academic outcomes (see Table 1). Structural relations are estimated using linear structural modelling analyses (Amos) (Arbuckle & Wothke, 1999).

The present study revealed several general findings concerning the family-study interface (see Figure 1). First, it was shown that the more students participate in family activities (e.g., spending time with family, household duties for the family), the more time-based conflict they experienced between their family lives and their lives as students. Second, family support negatively predicted time-, strain- and behavior-based conflict. In other words, the more students perceived support from the family, the less conflict they reported between their family and study. Third, the results indicated that involvement with the family is positively related to strain-based family-study conflict. This means that the more students were involved with the family, the more stress they seem to experience combining their family lives and their study. Contrary to expectations, the relationships between involvement with the family and time- and behavior-based conflict were non-significant.

As regards family-study facilitation, family support and the students' involvement with the family appeared to be antecedents of instrumental and affective family-study facilitation. In other words, the more students perceived family support and the more students were involved with the family, the more family-study facilitation they reported. Our study also demonstrated that students' effortful behaviors and school satisfaction are affected by the family-study interface. Time- and behavior-based conflict negatively affect students' effortful behaviors, which on the other hand were positively, and more strongly, affected by affective family-study facilitation. Students' school satisfaction was negatively predicted by strain-based family-study conflict and positively, and again more strongly, by affective family-study facilitation. Finally, academic performance was positively predicted by effortful behaviors and study satisfaction, with effortful behaviors being the strongest of both predictors.

In sum, the results of the present study show that known antecedents of the family-work interface also operate in the family-study domain and that conflict and facilitation, as extensively studied between family and work, also exist between family and study. Furthermore, it was found that experienced family-to-study conflict and family-to-study facilitation relate to students' school performance.

This study has several implications for research on interrole processes and on the relationship between family and study in particular. Most studies on interrole processes to date have focused on the relationships between work and family (Ford et al., 2007; Greenhaus & Beutell, 1985; Greenhaus & Powell, 2006; Wayne et al., 2007). Studies on the relationship between work and a non-work role such as school (Butler, 2007; Markel & Frone, 1998) have only recently been conducted. However, no prior studies have shifted these theories on interrole processes away from the work domain and applied them to non-work domains such as family and school. The results of the present study show that processes of conflict and facilitation, as extensively studied between family and work, also exist between family and study.

Second, this study shows the importance of family in the lives of students in higher education. Family support reduces the conflict experienced between family and study and increases the family-study facilitation experienced, which in turn positively impacts study effort and ultimately students' grades. Involvement with the family enhances both instrumental and affective family-study facilitation, resulting in more study effort, school satisfaction and in the end in higher grades. These positive contributions of family involvement on facilitation seem to outweigh the negative impact of strain-based family-study conflict resulting from higher levels of involvement with the family. In terms of opportunities to improve academic success (higher grades), support for involvement with the family and creating family support are probably effective policy measures.

PAPER PRESENTATION

The learning life course of at 'risk' children aged 3-16: Perceptions of students and parents

Iram Siraj-Blatchford, Institute of Education - University of London, United Kingdom

The paper reports on 50 Child and Family Case Studies (CFCS) that were conducted as part of the Effective Provision of Pre-School, Primary and Secondary Education (EPPSE) research project. The CFCS was designed as a mixed-methods study in order to look at why and when certain children manage to succeed 'against the odds' while others do not. Using in-depth interviews with students, parents and teachers, quantitative data available from EPPSE and a literature review on risk and resilience, the CFCS provides 'thick descriptions' and explanations of how child, family and school factors interact and contribute to children succeeding against the odds of disadvantage. The study shows that in families with children succeeding against the odds, parenting is characterised by 'active cultivation' and that schools, teachers, peers and the wider community contribute to children's academic success by providing emotional, practical and relational support. As a result these children are facilitated and encouraged to develop a combination of positive cognitive and socio-behavioural characteristics that helps them become active agents in their learning life-course. The CFCS provide information that can be of use to both policymakers and practitioners. It has implications for parenting and home-school relations and may serve to inform policies and practices that aim to increase the chances of children 'at risk' and help in closing the gap between those who are academically and socially advantaged and disadvantaged.

Background

The Effective Provision of Pre-School, Primary and Secondary Education (EPPSE) research project is a large scale, longitudinal, mixed-method study that has followed the progress of 3000+ children from the age of 3 to 14 and will continue to do so beyond the end of their compulsory schooling (age 16 in the UK). An ongoing focus for EPPSE is the extent to which pre-school, compulsory education and children's home learning experiences (HLE) can reduce inequality. While the study found that parents' socio-economic status (SES) and levels of education were significantly related to child outcomes, it also found that the quality of the HLE was important: it was what parents did that was more important in terms of the children's outcomes than who they were (Melhuish et al., 2001; Sammons et al, 2002).

A pilot study funded by the UK Cabinet Office focussed on disadvantaged children who were unexpectedly over-achieving at the end of primary education. It found that their families often had high aspirations and provided significant educational support that resembled 'concerted cultivation' (Lareau, 2003; Siraj-Blatchford, 2010).

In this paper we report on 50 mixed-method Child and Family Case Studies (CFCS) that were conducted when the children were in secondary education, in order to extend our understanding of how child, family and school factors interact and contribute to children's achievements.

Aims

The CFCS aimed to help us understand more fully the statistical patterns that have been found in the quantitative analyses of the EPPSE sample. The general question addressed in the CFCS was 'When and why do some 'at-risk' children succeed 'against the odds' while others fall further behind?', specifically looking at:

1. Key factors within families shaping educational outcomes of resilient and vulnerable children and how this varies with ethnicity;
2. The role of the school and teachers in enhancing or neglecting to promote children's academic and social potential at different ages i.e. leading to resilience or vulnerability;
3. Factors, external to school and family, that influence children's views of themselves as successful learners;
4. Views of vulnerable and resilient children and their parents of the children's educational experiences.

Methodology

In developing the CFCS we applied an adaptation of grounded theory. A systematic purposeful sample was obtained by using multilevel modelling on the EPPSE 3-11 sample (N=3172). Residual scores were created for each child, indicating differences in predicted and obtained academic achievement for English and Maths at age 11, while controlling for age, gender, birth weight, early developmental problems, parent education, social class and family

income (Melhuish et al., 2008). Three performance groups were created based on these residuals: 'succeeding against the odds', 'performing as predicted', and 'unexpected underachievers'. Family SES was then used to create four groups: socioeconomically disadvantaged children performing either as predicted or above prediction and advantaged children performing as expected or below prediction.

Two forms of analysis were conducted. Firstly the learning trajectories for English and Maths were identified for each child. Assessments spanning age 3 to 14 were ranked according to their relative position to the full EPPSE sample. Five general patterns described the trajectories: stability, improvement, decline, changeability and mixed (i.e. different trajectory for each subject).

Secondly, using NVivo software, interviews with 50 parents and students and 28 teachers were coded and analysed through an iterative process. Codes continued to be readjusted and redefined as we moved back and forth between the qualitative interview data, quantitative EPPSE data and relevant (inter)national literature on protective and risk factors.

Findings

The trajectories showed apparent differences between children before they started school. The succeeding children's initial rankings were relatively high and their trajectories were characterised by improvement. The general pattern of decline observed for more vulnerable children suggested a poor goodness-of-fit between their specific needs and the ability of schools, teachers and parents to tailor to these needs.

The systematic qualitative analysis identified protective and risk factors that influenced children's academic trajectories. Child related factors included perceived cognitive ability, self-regulation, psychological resilience, problem-solving strategies, intrinsic motivation, goal orientation and relationships with parents, teachers and peers. Positive attribution was associated with more successful adaptation to school and learning. The positive perception of the child as a learner was reinforced by parents, family, teachers, peers and the extended social environment. In contrast, negative attribution appeared to interfere with learning processes and contributed to and reinforced a sense of helplessness in children and (often) parents.

Parenting in families with children succeeding against the odds was characterised as 'active cultivation'. In these families parents provided rich (early) HLE experiences and went to great lengths to provide a broad range (extra curricular) learning experiences, often by enlisting their social network. These parents provided abundant practical, emotional and relational support for learning. They emphasized the importance of education, expressed consistent and high expectations regarding behaviour and (future) achievement and facilitated development of self-regulation skills, particularly for girls. From pre-school onwards, parents made it clear to their children that school and teachers were to be respected and perceived as important sources of learning.

High quality teaching (as perceived by children) helped students bond with teachers and encouraged them to achieve beyond their predicted attainment. How well schools were perceived to deal with children's specific educational needs reinforced positive or negative attitudes towards school and learning, both for students and parents. For vulnerable children, reports of high numbers of supply teachers and disorganized lessons were seen to have contributed to lower attainment.

Positive peer relationships and friendships facilitated academic success through emotional and practical support for children succeeding against the odds, while for others different forms of peer group/friendship relationships could reinforce negative attitudes to school and learning for academically less successful children.

Theoretical and educational significance

The CFCS provide information that can be of use to both policymakers and practitioners. It has implications for parenting and home-school relations and may serve to inform policies and practices that aim to increase the chances of children 'at risk' and help in closing the gap between those who are academically and socially advantaged and disadvantaged.

PAPER PRESENTATION

Scientific trends in the field of teacher education

Kristine Balslev, Universite de Geneve, Switzerland

This literature study deals with current researches in the field of teacher education. It is based on the analysis of articles published between 2005 and 2010 in *Teaching and Teacher Education*. It attempts to describe the scientific

trends in this field by pointing the main aims, the methodological approaches and tools, and the issues of the studies presented in these articles. Furthermore, it seeks to point out strengths and weaknesses of these studies.

Teacher education is an immense, current and increasing research field. The Educational Resources Information Center (ERIC) proposes around 10'000 articles having the expression - teacher education - in the key words published in peer-reviewed journals between 2000 and 2010 ; and numerous journals have - Teacher education - as a core subject (for example, *Teaching and Teacher Education*; *Journal of Teacher Education*; *Action in Teacher Education*; *Teacher Education Quarterly*; *Issues in Teacher Education*). A way to better know this research field is to make an analysis of recent scientific articles. There are many types of researches on the theme of teacher education and in order to have an overview of the kind of studies that are conducted in that domain and to explore the main trends in this field, we are conducting a literature study on the articles published between 2005 and 2010 in the journal *Teaching and Teacher Education*. We chose this journal because it is international and peer-reviewed. This journal publishes 8 issues per year, and each issue has between 7 and 40 original research articles. 730 original research articles written by authors from all around the world have been published in the five last years. It should well reflect the main trends of our domain of interest. The analysis of these articles consists in listing the key words and marking out theoretical concepts, theoretical frameworks, and resource - authors of the articles; identifying the main aims and issues (pragmatic, ontogenic, political or nomothetic, Van der Maren, 1996) of the studies the articles deal with. We are specially concerned with methodological aspects, therefore we identify these studies' approaches (qualitative, quantitative or mixed-designs); their main instruments (questionnaires, interviews, tests, reflexive journals, observations, videotapings, etc.); the number of subjects studied in the researches; the types of data gathered; and the way the data is analysed. The principal aim is to describe the types of scientific studies in this field, and to point out dominant types of researches as well as marginal ones. We started this analysis recently and our first findings (based on the analysis of 33 articles) show that nearly most (18 of 33) of the articles relate to studies that adopt an interpretative or qualitative approach (hermeneutic phenomenological research inquiry, comprehensive approach, case studies, narrative methodology, grounded theory methodology, ethnographic study, inductive analysis, self-study, autoethnography); less than a fourth (7 out of 33) can be considered as being experimental (using quantitative data and measures, and making statistical analysis such as hierarchical regression analysis or logistic regression); and fourth (8 out of 33) adopt mixed designs. We also noticed some recurrent and main aims, such as evaluation of teacher education programmes; description of teachers (or pre-service teachers) beliefs, values, emotions; description of teachers' reasonings; describing teachers' experiences and practices; the rate of satisfaction of pre-service teachers or new teachers; description and evaluation of effects teacher education programmes; understanding of teachers' professional identity construction. Our presentation will point out the aspects of teacher education that are recurrent in studies about teacher education and those that are absent; the strengths and weaknesses of studies conducted in the field of teacher education; the dominant theoretical frameworks; the authors and theoretical frameworks that researchers and this domain relate to. We will discuss the methodological features of these studies. We will also present future perspectives of this research, i.e. complete this analysis with the one of articles published in other European scientific journals, French scientific journals (for example *Repères*) and American ones (for example *Journal of teacher education*).

PAPER PRESENTATION

Perceptions Regarding the Accomplished Teacher among research and teaching oriented institutes

Irit Levy-Feldman, Kibutzim College, Israel; David Nevo, Tel Aviv University, Israel

Issues related to the "accomplished teacher", effective training programs and whether these programs are better taught at universities or at special teacher education colleges, are at the center of public debate in recent years, in Israel and elsewhere. The professional literature has described six core components of the accomplished teacher. These include three traditional components and three contemporary or modern components.

The aim of this study

To examine perceptions of the core components among teacher educators from universities and teacher colleges in Israel. It also looks at differences in these perceptions between schools of education and other faculties in the universities. Data was collected by questionnaire from a total of 523 staff members in research and teaching institutes in Israel. Quantitative method was used. The research findings carry both theoretical and practical implications. The currently prevailing notion of the effective teacher reflecting the complexity of teaching as it is now understood. In the present study these components can be traced back in the attitudes of teacher educators – whether in universities or at the teaching colleges. Furthermore, the study's results can give us some idea about the various advantages and drawbacks of teacher education in the different institutes – thus adding valuable findings to question regarding the desirable location of teacher education.

The purpose of the study

Teacher education takes place both in research-oriented and in teaching-oriented institutes. In Israel the difference between the institutes is clear cut. Teacher colleges are teaching-oriented institutes and universities are research oriented. Usually research oriented institutes enjoy higher academic status because they are seen to emphasize academic knowledge, generating new knowledge, research and criticism. Teaching institutes have relatively lower academic status, they are identified as pedagogical-professional in nature with a focus on practice, learning, interpersonal relations and collaboration. (Levy-Feldman, 2008; Niderlanc, Dror, & Hoffman, 2007). In addition, there is also evidence of differences within research institutes between schools of education and other faculties. Schools of education have a relatively low status in the research institute of which they are part (Goodlad, 1990a, b, 2002; Labaree, 2004, 2008; Levy-Feldman, 2004, 2008). The purpose of this study was to examine perceptions of core components of accomplished teachers, as they appear in the professional literature, among teacher educators from "research-oriented" and "teaching-oriented" institutes and, unlike other studies, this study looks also at differences in held perceptions between university-based schools of education and other faculties in the universities.

Theoretical Background

The literature describes six core components of the accomplished teacher (Carnegie Foundation, 1986; Holmes Group, 1986). The formulation of these components refers to both traditional and modern educational philosophies beginning with Dewey (1959) and developed by other educational philosophers (for example: Aloni, 2005; Fenstermacher & Soltis, 1986). One approach in traditional philosophy is cultural, regarding education as a process of acculturation. This philosophy considers education as part of the humanities and has been identified with the educational approach of research-oriented institutes) Darling-Hammond, 1987, 1997; Darling-Hammond & Snyder, 2000; Feiman-Nemser, 1990; Shulman, 1987; Zeichner, 1994). Teacher training emphasizes the teacher's subject matter knowledge and the pedagogical skills specific to the subject matter (Darling-Hammond, 1987). According to the second traditional approach, social philosophy, education is a tool in the service of socialization, Fenstermacher and Soltis (1986) describe this approach as "the executive approach". The main goal is to transmit knowledge. Teacher training emphasizes teaching theories and techniques and promotes teachers' general pedagogical skills (Cochran-Smith, 2004). This philosophy has been identified with the educational approach of teaching-oriented institutes (Feiman-Nemser, 1990; Cochran-Smith, 2004; Zeichner, 1994). From the 1990s a modern, student-centered philosophical approach towards education developed (Aloni, 2000; Dewey, 1959; Fenstermacher & Soltis, 1986). The goal of education, here, is to create the optimal conditions for self-growth with no direct connection to cultural or social goals. The accomplished teacher is required to be committed to the full diversity of students and their learning. Such a teacher is called a "caring" teacher (Noddings, 1999), and his professional development fosters the ability to critically examine his own practice (reflection) (Silberstein, 1998) as well as to cope with and adjust to ongoing changes. Hence Shulman's (2005) notion of the "pedagogy of uncertainty". To be able to acquit himself of this, the accomplished teacher also must be involved in a learning community. Modern approaches are not clearly identified with either research or teaching institutes. But when looking at what the literature describes as good teacher education - broad and authentic practice, teaching research, staff and institute support (Darling-Hammond, 2005, 2006; Feiman-Nemser, 1990; Goodlad, 1990a; Howey & Zimpher, 1989) - it would seem that teaching institutes are more likely to train accomplished teachers (Levy-Feldman, 2008).

Research questions and hypothesis

The first research question examines differences between staff members in research and in teaching institutes regarding components of the accomplished teacher. We hypothesized that staff members from research institutes will emphasize traditional components especially those that are associated with their institute. Teaching institutes will mainly emphasize modern components but also general pedagogical skills, a traditional component that can be attributed to teaching institutes. The second research question examines differences regarding the components between three groups of staff members: from teaching institutes, university-based schools of education and other faculties in the universities. We assumed that staff from school of education in the research institutes and from teaching institutes would resemble each other more than staff in other faculties of the research institutes. MethodData was collected by questionnaire from a total of 523 staff members in research and teaching institutes in Israel. Quantitative method was used. The questionnaire was validated both through a pilot study as well as in the subsequent study.

Findings and implications

Data analysis supports the main research hypothesis. Faculty members in teaching institutes emphasize what we defined as modern components, while faculty members in research institutes emphasize traditional ones. However, when we look within research institutes, the outcomes change. While science and humanity faculties rank traditional components highly, schools of education emphasize both modern and traditional components. Findings show that participants from both teachers colleges and schools of education in the universities attribute high significance to

modern components of the accomplished teacher. In teachers colleges the emphasis is mostly on the teacher's commitment to students and their learning, as well as to cooperation and membership in learning communities. Schools of education focus mainly on the teacher's professional development. In addition, schools of education attribute high importance to the teacher's subject matter knowledge. In this they differ from teachers colleges as well as from their colleagues in the other faculties of the research institutes. Practical and theoretical significance These findings carry both theoretical and practical implications. The currently prevailing notion of the effective teacher includes a core of traditional as well as modern components, reflecting the complexity of teaching as it is now understood. In the present study these components can be traced back in the perceptions of teacher educators – whether in research or at the teaching institutes. They can, indeed, be used to evolve a profile of the good teacher and as such contribute to the ongoing debate on this issue. Moreover, the broad view taken by this study, taking into account the various actors in teacher education, allows better understanding as well as more accurate comparison between research and teaching institutes, and therefore more valid conclusions and recommendations. Furthermore, our results reveal that the idea, reflected in policy-level recommendations in Israel, regarding a connection between type of institution, the accomplished teacher and the best mode of training in teacher education, is misguided. The present results can give us some insight into the various advantages and drawbacks of teacher education in the different institutes under examination – thus adding valuable findings regarding the issue of the desirable location of teacher education, indicating that settings are more than just sites (Houston, 2008; Robinson, 2008; Zeichner, 2008; Zeichner & Conklin, 2008).

PAPER PRESENTATION

Using Video to Assess the Development of Professional Vision in Teacher Education

Kathleen Sturmer, School of Education, Germany; Geraldine Blomberg, TUM School of Education, Germany; Tina Seidel, Technische Universität München, Germany

There is a general consensus among researchers and teacher educators that video has the potential to be a valuable tool for supporting pre-service teacher learning. Thus, video has become a popular resource in teacher education. This study presents how video can be used to assess development of professional vision in the context of pre-service teacher education. Teachers' professional vision is the ability to engage in knowledge-based reasoning about components of effective teaching and learning in the professional observation of classrooms. Professional vision is a critical component of teachers' expertise and thus should be developed during teacher education. We developed an internship-term to foster professional vision by supporting the integration of theoretical knowledge (video-based university courses) and conceptual knowledge (practical experiences at school). Development of professional vision was assessed via the video-based, yet standardized online tool Observer in a pre-/post design with N=110 pre-service teachers. Our findings indicate substantial gain of professional vision over the course of the four-month internship-term and present a useful concept as well as design to foster professional vision at an early stage of teacher education programs.

Introduction

Professional vision is an important component of teacher expertise (Goodwin, 1994). It describes teachers' ability to apply their knowledge of teaching and learning processes in order to notice and interpret significant features of classroom situations (van Es & Sherin, 2002). However, teacher candidates during teacher education are often not yet able to reason about key elements of classroom instruction (Star & Strickland, 2008). When it comes to foster professional vision, previous studies have shown that video-based trainings can help teachers to engage in knowledge-based reasoning on teaching and learning processes in authentic contexts (Sherin & van Es, 2009). However, these programs are mostly targeted on experienced teachers. Few studies have assessed the impact of video-based trainings of professional vision for pre-service teachers at the beginning of their careers (van Es & Sherin, 2002; Star & Strickland, 2008; Santagata & Guarino, in press). Furthermore, the findings available do not derive from standardized studies wherefore they do not allow general conclusions to be drawn about specific conditions under which teacher candidates develop professional vision in video-based teacher education programs (Star & Strickland, 2008). To systematically foster and study pre-service teachers' development of professional vision in a video-based way, several characteristics of professional vision need be considered. Professional vision is a strongly knowledge guided process (Palmeri, Wonn, & Gauthier, 2004) what requires to offering specific theoretically knowledge about teaching and learning. Furthermore, with regard to pedagogy, the development of professional vision can only occur through a contextualized generalization of knowledge in the course of practical experience (Putnam & Borko, 2000). In addition, we need some degree of standardization to assess growth and to analyze how to foster pre-service teachers' professional vision (Kersting, 2008). This led us to (1) develop an intervention (internship-term) that fosters the integration of conceptual and practical knowledge and (b) to evaluate this intervention with a tool that combines contextualizing video prompts with standardized rating items. Against that background, we investigate how professional vision develops over the course of the internship term.

Internship-term

The four-month internship-term combines elements of practical experience at schools and course work at university. The university course offers theoretical input and use of video-based examples to successively deal with the educational content of effective instruction (goal clarity, learners' support, learning climate). To assure best learning conditions in class, the sample of pre-service teachers was (randomly) divided into three classes. All classes were based on the same curriculum but since they took place simultaneously, they were taught by different instructors. The instructors were trained together and evaluations show no difference between the instructional quality of the three classes.

Sample

The N=110 pre-service teachers from the three different course-groups do not differ significantly in their relevant student characteristics and theoretical and practical pedagogical experience. They thus could be treated as one single sample group. Overall, the mean age of the participants was 21.43 (SD = 1.42), 65.8 % were female; in average they were attending their 4th semester of study program (SD = .21). Measure: ObserverThe computer-based online tool Observer was developed to measure teachers' ability to apply their knowledge to evaluate videotaped classroom situations. Participants were presented six video clips showing classroom interactions and, based on their concepts of instructional quality, asked to evaluate these situations on 121 items using a four-point Likert-type scale ranging from 1 (disagree) to 4 (agree). Items focussed on three sub-dimensions that research has distinguished in the process of knowledge-based reasoning: (a) description, (b) explanation, and (c) prediction. Participants' ratings of the video clips were compared with expert ratings (hit = 1/miss = 0). The Observer proved to be highly reliable (Cronbach's alpha in the present sample: .92). For further information see Seidel, et al. 2010. Selected ResultsPre-service teachers' professional vision develops over the course of the internship-term. Analyzing pre-/post-scores of knowledge-based reasoning in a MANOVA indicates significant growth ($F(1, 110) = 10.28, p$

Conclusions

Professional vision develops over the course of the internship term, mainly in the aspect of prediction what is the most knowledge-based facet of knowledge-based reasoning compared to description and explanation. Our findings show that linking practice (experiences at schools) to theory (knowledge about teaching and learning) shows potential in fostering professional vision in pre-service teacher education.

PAPER PRESENTATION

A Taxonomy of Educational Knowledge for University Teacher Education: A Delphi Study

Olga Kunina-Habenicht, Johann Wolfgang Goethe-University, Germany; Mareike Kunter, Goethe-University, Institute of Psychology, Germany; Hendrik Lohse-Bossenz, Goethe-University, Germany; Jurgen Baumert, Max Planck Institute for Human Development, Germany; Detlev Leutner, Duisburg-Essen University, Germany; Ewald Terhart, Westfalische

Wilhelms-Universität Münster, Germany; Theresa Dicke, Duisburg-Essen University, Germany; Jill Goessling, University of Duisburg Essen, Germany; Franziska Schulze, Westfälische Wilhelms-Universität Münster, Germany; Doris Foerster, University of Frankfurt, Germany

Foundations of professional teacher competence are laid in the theoretical part of teacher education, which aims particularly at providing content knowledge, pedagogical content knowledge, and pedagogical knowledge in formal learning settings. For subject-specific knowledge, several researchers have suggested taxonomies of content and pedagogical content knowledge, showing the practical relevance of these taxonomies in teaching situations. However, for subject-unspecific educational topics such taxonomies do not yet exist. This paper describes a Delphi study that aims at developing the taxonomy of core educational topics that should be taught in university teacher education. The Delphi study consisted of three consecutive rounds involving 48 experts of various professional backgrounds. Results of the Delphi study show that experts from different disciplines involved in German teacher education share an understanding of topics relevant to the training of prospective teachers. Based on the resulting taxonomy of core educational topics, a standardized instrument is currently being developed, for use in a longitudinal study to track the professional development of prospective teachers.

Theory

There is a consensus that teachers' success in providing high quality instruction is connected to their profession-specific declarative and procedural knowledge (Baumert et al., 2010; Shulman, 1986). Thus, the foundations of professional competence are laid in the theoretical part of teacher education, which aims particularly at providing content knowledge, pedagogical content knowledge, and pedagogical knowledge in formal learning settings. While the importance of the professional knowledge base per se is uncontested, it is less clear how the relevant knowledge should be taught, and which content such a knowledge base should include (Zeichner, 2005).

Most teacher education systems are structured in two consecutive parts: university and practical induction. University education has often been criticized for providing insufficient practical preparation, and for teaching theoretical knowledge that is perceived as practically irrelevant (Cochran-Smith & Zeichner, 2005). However, given the high complexity of teachers' actions in rapidly changing situations with high demands on reflection ability, we argue that a thorough conceptual understanding of the domain and of educational topics is the key to improving teachers' assessment skills (Rittle-Johnson, Siegler, & Alibali, 2001).

In order to test this hypothesis, a theoretical framework that describes the aspects comprising the "conceptual understanding" is needed. For subject-specific knowledge (e.g. mathematics) several researchers have suggested taxonomies of content and pedagogical content knowledge showing the practical relevance of these taxonomies in teaching situations (Baumert, et al., 2010). For the subject-unspecific part of teacher education such taxonomies do not yet exist. Hence, this paper describes a Delphi study that developed a taxonomy of core educational topics that should be taught in university teacher education. Based on this taxonomy a standardized test instrument will be developed to assess educational knowledge of prospective teachers.

Research questions

- 1) Do experts from different disciplines in teacher education share an understanding of relevant topics in teacher education?
- 2) Which topics comprise the potential taxonomy of educational knowledge?

Methods

The study took place in Germany, where teacher education is structured in two parts: university and practical induction. The expert panel consisted of 35 university lecturers and 13 experts involved in practical training and teaching practice. University lecturers were selected from the disciplines of Education, Psychology, and Sociology. Experts participated in a paper-pencil Delphi study in which they rated the importance of educational topics in three consecutive rounds. In the first round 213 educational topics, collected from detailed curriculum analyses of teacher education programs and textbooks, were presented. They covered the following nine areas: Instructions, Educational theory, Educational system, Teacher profession, Developmental processes, Socialisation processes, Learning processes, Heterogeneity, Diagnostics.

Within each area, specific topics were listed (e.g., within the section Instruction "Teacher-student interaction models"). The aim of the Delphi study was to reduce the list of topics to a core taxonomy consisting of topics with high relevance ratings. Consensus between panel members was estimated using the Average Deviation Index (ADM, Burke, Finkelstein, & Dusig, 1999) that measures within-group agreement. The procedures of each Delphi round are reported in the next section.

Findings

In the first round experts rated the relevance of all topics on four dimensions (understanding the academic discipline, understanding the teaching profession, analyzing situations, practical application) on a three-point scale (1–negligible; 2–helpful; 3–necessary). Experts also had the opportunity to add missing topics. The results revealed reasonable agreement among the whole panel as well as in most expert subgroups (see table 1 in appendix). The expert panel did not mention any missing topics, indicating that the presented canon of topics was exhaustive.

In order to reduce the number of relevant topics in the second round, experts had to choose a range of topics to be taught at university within a given time and to choose a range of topics relevant for practical application. The presented topics were ranked by the results of the first round, with the most important topics presented first. This round resulted in a further differentiation of the relevance of the topics.

The third round provided experts with the information on how many experts had chosen the particular topic. Furthermore, members of the expert panel received feedback on their individual choice in the previous round, in order to initiate deep level processing when forming a decision. As intended, the third round resulted in increasing consensus within the expert panel. Based on these final ratings, topics that were chosen by the majority of the expert panel with respect to either university teaching or practical application were considered as representing core educational topics in teacher education. Overall, 104 of the 213 original topics formed this core knowledge base.

Relevance

Our results show that experts from different disciplines involved in teacher education share an understanding of the educational issues most relevant to teacher training. Thus, despite various professional backgrounds, experts agree that a conceptual understanding of core topics in educational science, psychology, and sociology provides prospective teachers with a good preparation for professional life. Based on the final topic taxonomy, a standardized instrument is currently being developed for use in a longitudinal study to track the professional development of prospective teachers. This study will allow reliable statements about the impact of educational knowledge on later professional success.

PAPER PRESENTATION

Fostering Self-Regulated Laboratory Tasks by Video Demonstrations and Incremental Scaffolds

Florian Schmidt-Weigand, University of Kassel, Germany; Martin Haenze, Institut für Psychologie, Germany; Karsten Rincke, University of Regensburg, Germany; Rita Wodzinski, University of Kassel, Germany

The research project aims to explore two instructional means for supporting self-regulated laboratory tasks: (a) video demonstrations to instruct experimental skills and (b) incremental scaffolds for laboratory tasks. First, we present the results of a study on the effectiveness of videos to moderate students' experimental skills. One-hundred and eighty-five junior high-school students saw either one of two videos for different subject matters (mechanics, electricity) and completed tests (retention, transfer) for both subject matters. Students performed better on retention (i.e. planning and obtaining observations) when they had seen the respective video. Results for the transfer tests were mixed. A second study which was run in October/November 2010 aimed to explore incremental scaffolds in self-regulated laboratory tasks and possible interactions of the giving or withholding of such scaffolds with experimental skills (manipulated by video demonstrations). The results of this second study will also be presented and discussed.

In laboratory tasks students often have to follow laboratory guides prescribing each step of an experiment (Hofstein & Lunetta, 2004). These cookbook-like guides bear resemblance to worked examples which have been shown to support initial skill acquisition in well-structured domains such as mathematics, physics, and programming better than unguided problem-solving (e.g. Corey, Bennell, Emeno, & Martens, 2009). Worked examples and laboratory guides ("worked experiments"), however, may not foster self-regulation, cognitive activation and inquiry. These learner activities are of particular importance to achieve the goals of laboratory tasks, which may be a reason why students' laboratory work often falls short of expectations (Hucke & Fischer, 2002). Concerning worked examples, learners can be activated by presenting the example steps incrementally, on demand, and preceded by strategic prompts. These incremental scaffolds have been shown to increase the effectiveness of worked examples (Schmidt-Weigand, Hänze & Wodzinski, 2009). It appears reasonable to assign such incremental scaffolds to laboratory guides.

Laboratory tasks may also be ineffective because students lack basic experimental skills (handling the apparatuses, planning experimental steps, obtaining and documenting viable observations, etc.). Those skills can be instructed by the teacher or in a demonstration video prior to the students' laboratory work.

In this research project we explore the effects of problem-solving scaffolds for laboratory tasks, and video demonstrations on students' self-regulated laboratory work. Besides simple main effects, one may expect interactions between scaffolds and the matter of experimental skills. Before these interactions can be explored, it is necessary to test if experimental skills can effectively be manipulated by a video.

In a first study, 185 junior high-school students (7th to 9th grade) saw one of two videos demonstrating (a) how to obtain extension characteristics of a spring using different weights (mechanics) or (b) how to obtain the amperage for different voltages in an electrical circuit with an omic resistor (electricity). The study followed a 2x3-design with the between-subjects factors video (mechanics, electricity) and grade level (7th, 8th, or 9th grade). Each student saw one video and completed retention ("What do you have to do if you want to explore the characteristics of a spring/a consumer load ...?") and transfer (e.g. "How can you obtain an unknown mass/voltage when you have measured the extension of the spring/the amperage in the electrical circuit?") tests for both subject matters.

Separate ANOVAs for mechanics and electricity retention as dependent measures, respectively, and with the between-subjects factors 'video' (seen vs. not seen) and 'grade level' revealed the following results. Students performed better in both retention tests when they had seen the respective video compared to those students who had not seen the video (mechanics: $F(1,173) = 18.33$, $p < .01$, $F(2,173) = 3.24$, $p < .05$, $F(2,179) = 15.92$, $p < .01$, $F(2,179) = 2.29$, $p = .16$).

ANOVA for the mechanics transfer test revealed significant effects of video ($F(1,173) = 12.98$, $p < .01$, $F(2,173) = 10.57$, $p < .01$, not seen the mechanics video). ANOVA for the electricity transfer test also revealed significant effects of video ($F(1,179) = 4.57$, $p < .05$, $F(2,179) = 5.40$, $p < .01$, $F(2,179) = 2.68$, $p = .07$), both main effects appear to be due to the 9th grade students who had seen the electricity video. Those students gained higher scores than any other experimental group. Experimental skills can be fostered by a video. As expected, grade level affects overall performance but concerning retention it does not interact with the effect of the video. While the effect in mechanics transfer is somewhat puzzling, overall transfer performance (10 to 30%) was low enough to conclude that the learning goals are not reached without further laboratory work.

In order to explore scaffolds for such tasks we currently conduct a second study following a 3x2-design with the between-subjects factors 'scaffold' (none, "cookbook", incremental) and 'video' (seen/not seen). The students receive a problem (e.g. an object with an unknown mass) which can be solved by generating appropriate observations (e.g. measuring and documenting the extensions of a spring for different known masses). The students either receive no guidance or they are guided by written instructions. This guidance is either given at once (i.e. a "cookbook") or incrementally, on demand, and preceded by strategic prompts (e.g. "What do you know or presume about the relation between the extension of a spring and the mass of an object?"). Similar to worked examples, a laboratory guide is expected to foster transfer performance compared to an unguided laboratory task. The incremental scaffolds, however, are assumed to promote self-regulation, cognitive activation and inquiry and, hence, should lead to the highest transfer performance. This effect may interact with experimental skills in that the differences between scaffolded and unguided laboratory tasks will be bigger if the students had not seen the video before. The study will be completed in November 2010 and results will be reported.

PAPER PRESENTATION

Self-Assessment and Task-Selection Training improves Self-Regulated Learning Outcomes

Danny Kostons, University of Groningen, Netherlands; Fred Paas, Erasmus University Rotterdam, Netherlands; Tamara Van Gog, Erasmus University Rotterdam, Netherlands

Students need to be able to accurately assess their own performance on a learning task and use this assessment for the selection of a new learning task for self-regulated learning to be effective. However, evidence suggests that students have difficulties with accurate self-assessment and task selection, which may explain why self-regulated learning often leads to poor learning outcomes. Experiment 1 investigated and confirmed the hypothesis that observing a human model engaging in self-assessment, task selection, or both could be effective for the acquisition of self-assessment and task-selection skills. Experiment 2 investigated and confirmed the hypothesis that acquisition of self-assessment and task-selection skills, either through examples or through practice, would enhance the effectiveness of self-regulated learning.

For self-regulated learning in which students are free to choose their own learning tasks to be effective, students should be able to accurately assess their own performance after completing a learning task, and to select a next learning task based on that assessment that is appropriate given their current level of knowledge or skill. However, students, and especially novices, may experience difficulties in assessing their own performance, due to high cognitive load, a lack of knowledge of assessment criteria and standards (Dunning et al., 2003), and a lack of knowledge on how to use assessment outcomes in combination with task characteristics to select new tasks (Kostons, Van Gog, & Paas, 2010). This may explain why self-regulated learning is often not effective for novices (Azevedo et al., 2008; Niemiec et al., 1996). Two experiments are presented here that investigated whether self-assessment and task-selection accuracy could be improved by means of training, and whether this would enhance the effectiveness of self-regulated learning. Experiment 1 investigated whether self-assessment and task-selection skills could be trained via examples, leading to higher accuracy of self-assessment and task selection on a test. A 2 x 2 design with the factors Assessment Example (yes/no) and Task-Selection Example (yes/no) was used. All 80 secondary education students (age M = 15.23, SD = .53) first completed a pretest, which did not show any differences between groups. Then they studied the modeling examples (see Van Gog & Rummel, 2010), in which models performed a learning task, and -depending on students' assigned condition- they subsequently observed the model engage in self-assessment, task selection, both, or neither (this control group had to find and correct mistakes made by the models). In total they saw four modeling examples. Finally, they completed a posttest, and after each problem on that test they assessed their own performance and indicated what new task they would select (but they did not get this task, the test was the same for all students). Results of a 2 x 2 ANOVA showed that students who had been trained on self-assessment, were more accurate self-assessors at posttest than students who were not ($F(1, 76) = 8.04$, $MSE = 33.08$, $p = .006$, $\eta^2_p = .10$) and the same applied to task-selection ($F(1, 71) = 11.57$, $MSE = 323.27$, $p = .001$, $\eta^2_p = .14$). There was no interaction effect. We also did not find any differences on posttest scores F , which was expected, as all learning tasks were the same for all student.

Experiment 2 investigated whether training self-assessment and task-selection skills would enhance the effectiveness of self-regulated learning. First, all 90 secondary education students (age M = 14.66, SD = .71) completed a pretest (showing no differences), then they received no training, training consisting of modeling examples (as in Experiment 1), or practice (instruction on self-assessment and task selection beforehand that they could then practice on the model's performance). Subsequently they engaged in self-regulated learning, working on eight heredity problems which they chose from a database containing 75 tasks. This database had tasks at five levels of complexity, each with three levels of support. Finally, participants completed a posttest. ANOVAs with planned contrasts showed that self-assessment and task-selection training, either through modeling ($t(87) = 2.68$, $p = .005$, one-tailed, $d = 0.64$) or practice ($t(87) = 2.27$, $p = .013$, one-tailed, $d = 0.61$) enhanced the effectiveness of self-regulated learning in terms of pretest to posttest learning gains. Training via modeling and practice seemed to be equally effective ($t(87)$ ns). Previous research on improving self-regulated learning in hypermedia environments has shown that training can improve students' application of self-regulation activities such as monitoring or planning during task performance and

that this can increase their learning outcomes (e.g., Azevedo & Cromley, 2004). Our study extends that research to self-regulated learning environments in which students can choose their own tasks, by showing that a relatively simple training intervention of self-assessment and task-selection can significantly increase learning gains attained through self-regulated learning.

PAPER PRESENTATION

Framing effects of informal learning sources on risk perception, emotions and learning

Christine Otieno, University of Freiburg, Germany; Alexander Renkl, University of Freiburg, Germany; Katharina Liebler, University of Freiburg, Germany; Ulrich Deil, University of Freiburg, Germany; Thomas Ludemann, University of Freiburg, Germany; Hans Spada, University of Freiburg, Germany

Internet and information brochures are important sources for informal learning. In contrast to learning materials used in formal curricula these sources are often written in journalistic styles. Effects of these styles on the perception of information have been investigated within the framework of media effects, in particular within research on framing theory. In the present study we broadened existing research by focusing on the effects of different news frames, in particular a rather sensational vs. an expository representational style, on learning outcomes. Seventy-two students in two conditions (sensational vs. expository) read five brochures about climate change and invasive species. They rated their emotions and risk perception in reaction to the information presented, and they completed a posttest with multiple-choice items and open questions. As expected, the sensational condition showed higher risk perception and stronger negative emotions compared to the expository condition. In addition, a sensational style also led to better learning outcomes (multiple choice test). Furthermore, participants in the sensational condition prioritized in particular negative aspects in answers to open questions when asked what information they considered most important. Taken together, our results indicate that while a sensational style enhances learning it might lead to a rather negative and one-sided instead of a well-informed and balanced view.

Informal learning plays an important role in lifelong learning. The term informal learning refers to learning activities outside formal curricula and without direct reliance on a teacher. It is typically interest-guided and self-directed (Livingstone, 2006). Given that most informal learning sources such as the internet and information brochures are influenced by journalistic styles it seems important to investigate informal learning effects in an interdisciplinary framework. Framing theory provides such a framework in which one can investigate the effects of different news frames on audience's interpretation and evaluation of information. According to de Vreese (2005, p.53), "a frame is an emphasis in salience of different aspects of a topic" and is concerned "with the presentation of a topic". Different framing leads to different emotional reactions as well as different focus in thoughts about a topic. Framing effects have to be distinguished from information effects, that is, effects of the core facts of information. To our knowledge, there is hardly any research about framing effects on learning. One exception is Valkenburg, Semetko, and de Vreese (1999) who found negative effects of the human interest frame (i.e., a personalizing and dramatizing frame) on recall (multiple choice test).

In the present study we tested the effects of a rather sensational presentation (dramatizing aspect of the human interest frame), to a rather expository presentation of the topic of climate change and invasive species in information brochures in a pretest-posttest design. The length of texts and basic information as well as the pictures included were held constant across conditions. Dependent variables were elicited emotions, risk perception, and learning measured with a multiple choice test and open questions.

Method

Seventy-two students of psychology (age: $M = 22.60$; $SD = 4.42$) were randomly assigned to the sensational condition (dramatizing frame, using expressions like "extreme dangers"; 36 participants) or the neutral condition (expository frame, using expressions like "possibly problems"; 36 participants). Participants completed a pretest on knowledge about and perception of climate change as well as of local invasive species. They then read their respective versions of five short information leaflets: one about climate change, which served as an introduction to the topic, two about invasive plants, and two about invasive animals. After reading each leaflet students were asked to rate their emotions on four 5-scale items (1= not at all angry/sad/guilty/affected to 5= very angry/sad/guilty/affected) as well as their risk perception on seven 5-scale items. Finally students completed a posttest consisting of five open questions ("Which do you consider the three most important aspects you would tell a friend about...?") and six multiple choice items on the information presented in the brochures. Answers to open-ended questions were segmented and coded differentiating between positive, negative, and neutral statements about topics covered.

Results

Risk perception was significantly higher ($F(1, 67) = 63.48$, $p < .001$), and negative emotions (anger, guilt, and sadness) were significantly stronger ($F(1, 67) = 6.44$; $p < .01$) in the sensational condition as compared to the expository condition (ANCOVAs controlling for prior risk perception). Additionally, tests for a mediation effect of risk perception on negative emotions indicate that risk perception functioned as a mediator between the way information was presented and negative emotions ($a*b = -.51$, $LCL = -.80$, $HCL = -.21$, $zab = -3.37$, $p < .001$). The direct effect of different styles on emotions was no longer significant when controlling for risk perception.

Regarding learning outcomes, students in the sensational condition showed a significantly better performance in the multiple choice posttest ($F(1, 67) = 4.64$, $p < .05$). Additionally, there was a difference in students' prioritizations in their answers to open questions: Students in the sensational condition made significantly more statements about negative aspects, $F(1, 67) = 56.00$, $p < .001$, whereas students in the neutral condition made significantly more statements about positive, $F(1, 67) = 70.38$, $p < .001$, and neutral aspects, $F(1, 67) = 12.46$, $p < .01$ (ANCOVAs controlling for prior knowledge).

Discussion

Up to now, research has rarely focused on effects of journalistic styles on learning. Given the increasing importance of, and the role media plays in informal learning more insight is needed about these effects. In our study, a sensational style improved learning outcomes. However, answers to open questions indicate that sensational style lead to the prioritization of negative aspects. These findings indicate that the style in which information is presented not only influences how much is learned but also what kind of information is emphasized. Similar to social cues in the personalization principle of Mayer (e.g., 2003), sensational style seems to increase memory for the rather sensational aspects taught. At the same time sensational style seems to distract from positive and neutral aspects. In analogy to the effect of seductive details (e.g. Harp & Mayer, 1998) this effect could be termed as seductive emphasis. However, before we can establish a seductive emphasis effect, findings have to be replicated.

The positive effects of sensational style on learning we found contradict Valkenburg et al. (1999) who found a negative effect. This divergence might be due to the specific framing used. Whereas Valkenburg emphasized the effects on an individual (i.e., focused on the "personalization aspect" in the human interest frame), we utilized dramatizing vocabulary as a means of sensitization. Against this background, we are presently conducting a second study comparing the effects of three different "sensational news frames" ("sensational- drama", "sensational - emotion" and "sensational- personalization") and an expository "control frame".

PAPER PRESENTATION

Assessing Cognitive Load with Subjective Rating Scales: Is the whole more than the sum of its parts?

Annett Schwamborn, Duisburg-Essen University, Germany; Maria Opfermann, Duisburg-Essen University, Germany; Tamara Van Gog, Erasmus University Rotterdam, Netherlands; Fred Paas, Erasmus University Rotterdam, Netherlands; Detlev Leutner, Duisburg-Essen University, Germany

Subjective cognitive load (CL) ratings are widely used in educational research. However, it is currently unclear, whether to measure CL repeatedly during learning or problem solving, or only once afterwards. To investigate if these two methods are comparable and thus reliable indicators of the actual load experienced, 172 students worked through a sequence of six problems. CL was assessed by means of mental effort and perceived task difficulty after each problem and after the whole process. Results show that the two retrospective scores are significantly higher than the means of the respective six scores assessed during problem solving. This might point to an overestimation when assessing CL only once retrospectively and speaks in favor of measuring CL continuously during learning.

Objective and Theoretical Framework

Research on Cognitive Load Theory (CLT; Sweller & Chandler, 1991; Sweller, 1999, 2005) has recently been accompanied by discussions regarding the measurement of CL. For subjective rating scales, learners are typically asked to rate their invested mental effort (Paas, 1992; Van Gog & Paas, 2008) or perceived task difficulty (Kalyuga, Chandler, & Sweller, 1999; Mayer & Chandler, 2001) on a 7- to 9-point Likert scale.

Some open questions remain regarding the use of subjective ratings, e.g., when to apply such scales (van Gog, Kirschner, & Paas, 2009). Whereas some studies assessed CL as a retrospective, overall measure (e.g. Kalyuga et al., 2001; Schwamborn, Thillmann, Opfermann, & Leutner, in press), others used concurrent, online measures that were directly applied after each task (e.g. Tabbers, Martens, & van Merriënboer, 2004). Contrasting both, it seems reasonable to assess CL concurrently instead of retrospectively. First, it seems unclear what a single measurement once after learning reflects: estimations of learners' invested mental effort as an average over all tasks, the last task, or the most complex task? Additionally, one retrospective rating cannot give information on fluctuations in CL over time (van Gog et al., 2009). However, before investigating what both measures reflect, it is necessary to investigate whether there are actually differences between the average of concurrent vs. retrospective scores. Van Gog et al. (2009) showed that a single mental effort rating after a sequence of problems results in higher scores than the average of ratings provided immediately after each problem.

The present study investigates whether there are differences between the average of concurrent scores and a retrospective CL score. We assume that single retrospective ratings of mental effort and perceived task difficulty after a sequence of problems result in higher scores than the average of concurrent ratings. That is, after learning, both task difficulty and mental effort are assumed to be overestimated.

Method

One hundred and sixty-eight undergraduate students participated in this study (mean age: 23.13 years, SD = 4.43; 68.5 % female).

Six so-called "weekday-problems" were used (e.g., "Suppose today is Tuesday. What day of the week is tomorrow?"; see also Sweller, 1993; van Gog et al, 2009). The element interactivity (intrinsic load) increased continuously from the first to the sixth problem.

CL was assessed with two subjective rating scales: the mental effort item by Paas (1992) and the perceived task difficulty item by Kalyuga, Chandler and Sweller (1999). Both items were answered on 7-point Likert scales.

A repeated-measures-within-subjects-design was used. Students were instructed to solve a sequence of six problems without taking notes, and had one minute to answer each problem. After each problem, invested mental effort and perceived task difficulty were rated immediately (concurrent rating). Additionally, after having completed all six problems, overall invested mental effort and perceived task difficulty were rated as well (retrospective rating).

Results and Conclusions

Means and standard deviations of performance, perceived task difficulty and invested mental effort are shown in Table 1.

Performance for each problem was rated as either correct or incorrect and scored with 0 or 1 points.

Mean scores for the respective six concurrent ratings regarding mental effort ($M=3.43$; $SD=.81$) and task difficulty ($M=2.96$; $SD=.81$) were compared to the overall scores reported retrospectively (mental effort: $M=4.32$; $SD=1.24$; task difficulty: $M=3.74$; $SD=1.16$). Two paired samples t-tests reveal that retrospectively both, mental effort, $t(167)=13.54$; p .

These findings confirm our expectations with regard to the overestimation of invested mental effort and perceived task difficulty when being assessed retrospectively. This is also supported by the results of two multiple linear

regression analyses (cf. Tables 2 and 3), in which the retrospective ratings of invested mental effort and perceived task difficulty were predicted with the respective six concurrent ratings. The strongest predictors of retrospective ratings are in both cases the ratings for the 4th, 5th and 6th problem, which are assumed to be more complex than the 1st, 2nd and 3rd problem. This interpretation has to be taken with care, however. Even though, as could also be concluded from performance scores, the last problems appear to be more complex and, thus, the overestimation hypothesis seems salient, it could as well be that this effect rather concerns the order of problems, e.g., a recency effect.

Discussion

This study aimed at shedding light onto the question, which point of measurement is suitable to assess CL for a sequence of increasingly complex problems. In line with expectations, the average of single concurrent ratings for invested mental effort and perceived task difficulty was significantly lower compared to an overall retrospective rating once after all problems had been completed. This difference points to an overestimation of CL when it has to be reported retrospectively - it seems that students in this case orient their ratings towards the ratings for the more complex problems. On the other hand, this effect could also be due to recency effects caused by the sequence of the problems (the last problems were designed to be more complex than the first ones) instead of being due to the problem complexity itself. However, since van Gog et al. (2009), who varied the order of problems in their experiments, did not find any impact of presentation order, but also an overestimation of retrospective mental effort scores compared to the means of concurrent scores, we agree with their conclusion that "the whole might be more than the sum of its parts". In either case, differences between average scores of concurrent ratings versus retrospective scores might get larger, the more problems have to be solved (that is, the longer such a sequence is) or the larger a learning unit is. In other words, retrospection abilities would likely be more stressed the more would have to be remembered for giving overall ratings after learning.

To sum up, our results support current CL research ambitions that plea for concurrent measures instead of assessing CL once after learning or problem solving.

PAPER PRESENTATION

Using a General Problem Solving Strategy in Mathematics to Facilitate Transfer

Amina Youssef, University of New South Wales, Australia; Paul Ayres, University of New South Wales, Australia; John Sweller, University of New South Wales, Australia

Recently, cognitive load theory has used the principles of evolution to argue that novel information is generated by a random generation process known as the randomness as genesis principle. In other words when faced with a problem, where no domain-specific knowledge is available, humans rely on general problem solving strategies. The aim of this study was to demonstrate that a general problem solver could be learned to facilitate far transfer effects. It was hypothesized that learners with little prior knowledge would benefit more from the general problem solving strategy in comparison to high prior knowledge problem solvers. During an acquisition phase 43 grade 9 students were either taught a general problem solving strategy to solve a set of geometry problems or required to solve problems without instructional help. On post-tests related to geometry, no difference was found between the two strategies. On a further test unrelated to problems linked to acquisition, there was an expertise reversal effect. Students with high mathematical knowledge were advantaged by an initial problem solving approach. In contrast, students with lower mathematical ability benefited from a general problem solving approach. This group had learned the general problem solving strategy and were able to transfer it outside the domain. In conclusion, this study suggests that students who lack domain specific knowledge can benefit from being guided by a general problem solver. In contrast students with more advanced domain-specific knowledge do not need such assistance because they can rely on that knowledge to generate problem solving moves.

The search for general problem solving strategies that transcend specific domains has been a goal of researchers in the field of cognitive processes and instructional design for a long time (Newell & Simon, 1972). The aim has been to find teachable/learnable strategies that students could acquire and then apply to all or most of the subject areas that they encounter. It is a search that has produced few outcomes. In contrast, cognitive load theory (CLT) has generated a number of instructional design effects based on the assumption that learning occurs due to the accumulation of a large quantity of domain specific knowledge in long-term memory. Recently, CLT has been linked to evolution (Sweller, 2004) and the role of general problem solving has been reconceptualized accordingly in the theory. Using the principles of evolution it has been suggested that novel information is generated by a random generation process known as the randomness as genesis principle. In other words when faced with a problem, where no domain-specific knowledge is available, humans have no choice but to rely on general problem strategies such as means-ends analysis. These general problem solving strategies enable humans to function in everyday life. However as domain-specific

knowledge increases in any particular domain, less reliance on general problem solvers are needed. This paper explores the use of a general problem solver in mathematics.

This study tested the hypothesis that students can be taught to use a random generation type strategy during problem solving. Geometry students faced with a conventional problem with a conventional goal such as "Find a value for Angle X" were instructed to ignore the goal and randomly calculate the value of as many angles as possible. These instructions were designed so that students could randomly calculate the value of as many angles as possible in the well-defined problem solving area of geometry. Previous work by Ayres (1993) provides evidence that problem solvers can more easily generate solutions to problems when they are presented in a goal-free format. Goal-free problems as opposed to conventional problems eliminate the use of complicated search routines been used to find a solution to a problem leading to a reduction in cognitive load. It was hypothesised that by following this instruction, students would learn to use a similar general strategy in unrelated areas, demonstrating the acquisition of a general problem solving skill. However, for students with prior knowledge in such unrelated areas would use schematic knowledge rather than a general problem solver.

Methodology

Participants

43 grade 9 students from a Sydney high school participated. Prior knowledge tests classified students as Higher or Lower Mathematical Ability. Students were randomly assigned to one of two experimental conditions (Conventional Problem and a General Problem Solver, GPS) creating a 2 (ability) X 2 (strategy) design.

Materials and Procedure

There were four sets of problems, one set for each of an acquisition phase, a test of similar problems, a test of unfamiliar problems and a test of unfamiliar far transfer problems. For the first 3 sets, questions required knowledge of basic mathematics geometry theorems. During the acquisition phase students in the GPS group were asked to "For each question, find as many angles as you can in any order you like". Students in the Conventional Problem Solving group were asked to "For each question, find the value of x". In the two testing phases, identical problems were given to both groups. The first test phase (similar problems) contained problems identical to those in the acquisition phase, except the size of the angles was changed. The second test phase (transfer problems) contained more complex geometry problems. In the far transfer test phase, the problems were designed to determine if students could solve problems in a different domain using their learnt strategy.

Findings

There was an ability main effect showing that the Higher Ability group performed significantly better than the Lower Ability group on acquisition, $F(1, 43)=46.8$, $p < 0.001$; test, $F(1, 43)=39.7$, $p < 0.001$; and transfer, $F(1, 43)=47.8$, $p < 0.001$. There was no main effect for problem solving strategy ($F<1$) nor an interaction ($F<1$) on acquisition, test and transfer. For far transfer, there was a significant main effect for ability where the higher ability group performed significantly better than the lower ability group: $F(1, 43)=10.4$, $p < 0.01$, but no main effect for strategy ($F<1$). However, there was a significant interaction: $F(1, 43)=10.9$, $p < 0.001$. Simple effects tests revealed that for high ability students the Conventional Problem group outperformed the GPS group, $t(25)=2.56$, $p < 0.05$. For the lower ability students the reverse effect was found as the GPS group outperformed the Conventional Problem group, $t(18)=2.15$, $p < 0.05$. For the higher ability students the mean scores for the Conventional Problem group were higher than the GPS group on each task. In contrast for the lower ability students the GPS group had higher scores indicating an expertise reversal effect (Kalyuga, Ayres, Chandler & Sweller, 2003).

Conclusion

From an instructional perspective, the current results suggest that students should be taught this general problem strategy. When faced with problems for which they do not have knowledge of a solution, this strategy can enhance problem solving performance. Nevertheless, it should not be seen as a substitute for domain specific knowledge. In conclusion, this study suggests that students who lack domain specific knowledge can benefit from being guided by using a random move generation strategy as a general problem solver. In contrast students with more advanced domain-specific knowledge do not need such assistance because they can rely on that knowledge to indicate appropriate problem solving moves.

PAPER PRESENTATION

Teacher activities in innovative and traditional teaching learning environments

Michelle Overman, Utrecht University, Netherlands; Jan Vermunt, Utrecht University, Netherlands; Astrid Bulte, Freudenthal Institute for Science and Mathematics Education, Netherlands; Paulien Meijer, Utrecht University, Netherlands; Mieke Brekelmans, Utrecht University, Netherlands

Abstract

Insights in educational and psychological theories have caused a shift in the understanding of learning, whereby learning is considered as a process of knowledge construction in stead of a process of knowledge transmission. Influenced by these insights, educational reforms in Dutch secondary education have brought more diversity in the ways schools organize their teaching learning environments (TLEs). As a consequence, the role of the teacher has been brought into discussion and is assumed to have changed as well, congruent with the educational reforms. In this study we aim to obtain an elaborate picture of teaching activities in innovative and more traditional teaching learning environments by studying teaching from multiple perspectives: an interpersonal, a learning activities and a content perspective. Three types of teaching learning environments were selected, which were expected to represent an optimal variety. This study included 21 chemistry teachers and their classes in three different types of TLEs in secondary education. Contrary to our expectations, the TLEs did not differ that much on these three perspectives as we thought. A first conclusion is that it is more important what a teacher does than in what TLE this teaching takes place.

Teacher activities in innovative and traditional teaching-learning environments from an interpersonal, a learning activities and a content perspective Michelle Overman, Jan D. Vermunt, Paulien. C. Meijer, Astrid M.W. Bulte & Mieke Brekelmans Department of Education, Faculty of Social and Behavioral Sciences, Utrecht University AimsInsights in educational and psychological theories have caused a shift in the understanding of learning, whereby learning is considered as a process of knowledge construction in stead of a process of knowledge transmission (e.g. Shuell, 1996). Influenced by these insights, educational reforms in Dutch secondary education have brought more diversity in teaching learning environments (TLEs) in schools. As a consequence, the role of the teacher has been brought into discussion and is assumed to change as well, congruent with the educational reforms (Bransford et al., 2005; Thadani, Stevens & Tao, 2009). In this study we aim to obtain an elaborate picture of teaching activities in innovative and more traditional teaching learning environments by studying teaching from multiple perspectives: an interpersonal (e.g. Wubbels and Brekelmans, 2005), a learning activities (e.g. Vermunt & Verloop, 1999) and a content perspective (Van Driel, Bulte & Verloop, 2007; Roberts, 1988). The research problem for this study is: How do teacher and students perceive teacher activities in different types of teaching learning environments from an interpersonal, a learning activities and a content perspective?

Methodology

In this study, three types of teaching learning environments have been selected (table 1), which we expect to represent an optimal variety in teaching activities from the content perspective and the learning activities perspective. We expect the interpersonal relationship to be more dependent on individual teacher level, rather than on type of TLE. We also expect this to be the case for affective activities. The TLEs are restricted to natural classroom settings and the subject chemistry. For each type of teaching learning environment 7 experienced chemistry teachers in secondary education were selected with one of his/her fourth year classes (students age 15-17) of senior general secondary education. Questionnaire data from 517 students and 21 secondary education chemistry teachers in the Netherlands were obtained. Teacher activities were measured by means of questionnaires that map both teachers self perceptions and students' perceptions on the interpersonal, the learning activities and the content perspective. For the interpersonal perspective the Questionnaire on Teacher Interaction (QTI) from Wubbels et al. (1985) has been used. For the learning activities perspective a new instrument has been developed, based on the taxonomy of teaching and learning as described by Vermunt and Verloop (1999). This instrument is called the Questionnaire on Teaching Activities in Chemistry (QTA-C). This instrument demonstrated acceptable internal consistency (Chronbach's alpha's ranging from .80-.90). The content perspective has been measured with the Questionnaire on Chemistry Education (Van Driel, Bulte & Verloop, 2005). Currently, only ANOVAs have been performed to examine differences within and between TLEs. The procedure we will follow next is that data first will be analysed within single cases (teachers), next across cases within single TLEs and last between types of TLEs. Relations between teacher activities and cognitions will be analyzed by calculations of correlations and subsequent techniques.

Findings

It appeared that variances are larger on teacher level than between these three TLEs. Further, it was found there is a friction between teacher cognitions about their teaching and students' perceptions of teacher activities in most cases. In general, teachers considered their control to be more shared than students did. Further, teachers found it very important to relate chemistry to real life issues and knowledge development, while students do not experience chemistry in that way. Contrary to our expectations, the TLEs did not differ that much as we thought. A first conclusion is that it is more important what a teacher does than in what TLE this teaching takes place.

Theoretical and educational significance

This study may provide a more elaborated, detailed and specified description of teaching in different teaching learning environments than is currently available because it includes data on teacher activities from multiple perspectives. Furthermore, by using these three perspectives we wish to add to the empirical knowledge base for what really matters in teaching. In this way, we aim to contribute to the knowledge that can be used for enhancing professional development.

PAPER PRESENTATION

Enhancing approaches to learning: The added value of gradually implementing case-based learning

Marlies Baeten, K.U.Leuven, Belgium; Filip Dochy, K.U.Leuven, Belgium; Katrien Struyven, University of Brussels (VUB), Belgium

This study investigates whether a learning environment that combines both case-based learning and lectures can enhance students' approaches to learning, compared to the sole use of either case-based learning or lectures. Therefore, a quasi-experimental pre-test/post-test design took place in teacher education during a course on child development. Participants were 1099 first-year professional bachelor students. Research conditions were: 1) a completely lecture-based learning environment, 2) a completely case-based learning environment, 3) a mixed learning environment in which lectures and case-based learning were used alternately, and 4) a mixed learning environment in which lectures gradually made place for case-based learning. At the start and end of the course students' approaches to learning were measured. Results of analyses of (co)variance showed that the gradually implemented case-based setting was the most beneficial for students' approaches to learning. In comparison to the other learning environments, students in the gradually implemented case-based setting scored the highest on deep approach, monitoring and organised studying, and the lowest on surface approach.

Theoretical framework

A deep approach to learning, which aims at understanding, is highly valued in higher education. Previous research tried to enhance the adoption of deep approaches by implementing student-centred teaching, e.g. case-based learning (CBL) and problem-based learning (PBL). However, the results of these studies were not univocal (Baeten, Kyndt, Struyven, & Dochy, 2010). One possible explanation is that not the sole use of student-centred instruction encourages a deep approach, but instead the combination with lectures (Sivan, Wong Leung, Woon, & Kember, 2000).

Goals of lectures, e.g. structuring information, may offer support for disadvantages of student-centred teaching, e.g. a lack of structure and high workload (Struyven, Dochy, Janssens, & Gielen, 2008). Vice versa, the incorporation of active learning may minimise weaknesses of lectures, e.g. providing feedback about students' comprehension of the learning contents (Bonwell, 1996). The objective of the current study is to investigate the explanation of Sivan et al. (2000) that not the sole use of student-centred instruction encourages a deep approach, but instead the combination with lectures. The student-centred teaching method central to this study is CBL. Research question What is the influence of the teaching method (CBL, lectures or a combination of both) on students' approaches to learning?

Methodology

Participants were first-year professional bachelor students in teacher education who followed a course on child development. 26 teachers from 11 institutions for teacher education participated with their student groups (NStudents=1099 students). The design of the research was quasi-experimental. Each teacher and his/her student group were assigned to one research condition. 1) A completely lecture-based learning environment (LeLe) which comprised lectures, consisting of PowerPoint presentations, visual aids and teacher-student interaction. 2) A completely CBL environment (CaCa) in which students discovered the course content themselves by applying those contents necessary to solve authentic cases in small groups. 3) A mixed learning environment in which lectures and CBL were alternated (LeCaLeCa). About each development phase students received first a lecture and afterwards a case study. 4) A mixed learning environment in which CBL was implemented gradually (LeCaLeCa). The first chapters were provided by means of lectures, the next chapters were provided by means of a combination of lectures and CBL, and the final chapters were provided solely by means of CBL. Approaches to learning were measured by means of the Approaches to Learning and Studying Inventory (Entwistle, McCune, & Hounsell, 2002), which distinguishes between 5 subscales: 'deep approach'(a=0.75), 'surface approach'(a=0.72), 'monitoring studying'(a=0.65), 'organised studying'(a=0.79) and 'effort management'(a=0.75). The questionnaire was administered twice: at the beginning of the first course general approaches to learning were measured, and at the end of the final course approaches to learning child development were measured. Results ANOVAs and paired samples t-tests were conducted to answer the research question. Regarding deep approach, monitoring studying, organised studying and effort management, initial differences were found between the research conditions. In order to examine the effect of the research condition on these variables, ANCOVAs were conducted which controlled for initial differences in these approaches. Results showed a significantly higher deep approach in LeLeCaCa compared to CaCa and LeLe ($F(3,1094)=4.06$, $p\text{-value}=.01$). With regard to monitoring studying, students scored significantly higher in LeLeCaCa compared to CaCa and LeCaLeCa ($F(3,1094)=7.03$, $p\text{-value}=.02$). As to organised studying, significantly higher scores were found in LeLeCaCa compared to the other three settings ($F(3,1094)=12.64$, $p\text{-value}=.03$). Regarding effort management, ANCOVA could not be conducted since the assumption of homogeneity of regression slopes was not met. Concerning the surface approach, no initial differences were found between the research conditions. ANOVA showed that the surface approach was significantly lower in LeLeCaCa, compared to all other settings ($F(3,1095)=8.98$, $p\text{-value}=.02$).

Based on these findings, LeLeCaCa seemed the most beneficial in terms of students' approaches to learning. Nevertheless, this research condition did not have the power to enhance students' approaches. Instead, deep approach, organised studying and effort management remained the same and monitoring studying even decreased significantly. In the other research conditions, a significant decrease in monitoring studying was found too, next to a significant decrease in deep approach, organised studying and effort management. Regarding the surface approach, LeLeCaCa had the power to diminish this approach, just like LeCaLeCa. In the two other settings, the surface approach did not change. Conclusion Implementing CBL gradually was the most beneficial for students' approaches to learning. In comparison to the other learning environments, students in the gradually implemented CBL setting scored the highest on deep approach, monitoring and organised studying, and the lowest on surface approach. Nevertheless, the gradually implemented CBL setting did not encourage the use of deep approaches, monitoring studying, organised studying and effort management over time. Instead, these approaches remained the same or decreased significantly. Therefore, this research showed that it is difficult to enhance not only students' deep approach (Marton & Säljö, 1997) but also monitoring studying, organised studying and effort management. Possibly other variables might explain why no general increase is found in approaches to learning, e.g. student characteristics (Baeten et al., 2010).

PAPER PRESENTATION

The Effects of Two Contrasting Approaches to Peer Tutoring on Student's Learning

Inneke Berghmans, Catholic University of Leuven, Belgium; Filip Dochy, K.U.Leuven, Belgium; Katrien Struyven, University of Brussels (VUB), Belgium

Over the years, interest in different kinds of student-centred learning environments has grown. Among others, Peer tutoring has been reported to have diverse positive effects on students' learning. However, in order to understand these effects, they have to be considered in terms of the processes and dynamics occurring in this learning environment. In this respect, research is not clear on which approach to tutoring is more beneficial for students' learning. While some studies advocate the power of a facilitative tutor, other studies generate support for a more controlling and directive tutor. This study takes up the challenge to investigate the effects of these two diverse approaches to tutoring on students' approaches to learning, motivation and self-efficacy beliefs, and their related experiences with these approaches to tutoring. A quasi-experimental study was set up in a medical faculty that implements peer tutoring in the context of clinical skills training. The results did not verify the hypotheses in favour of the facilitative approach to tutoring. On the contrary, results indicated that students benefited more from a directive approach to tutoring, particularly in terms of their autonomous motivation. Moreover, medical students turned out to be less satisfied with a facilitative tutor and expressed diverse concerns related to this specific approach to tutoring. This research challenges the expected positivism of a facilitative approach as a discrepancy was brought to the fore between pedagogically and constructivist advocated practices, and the intended effects on students' learning.

Theoretical Framework

Peer Assisted Learning (PAL) has gained a lot of support over the years. However, while some studies support the notion of PAL stimulating a more deep approach to learning (Loke & Chow, 2005), others report that students tend to act more strategic-oriented after attending PAL-sessions (Ashwin, 2003). Among other things, the tutor and his approach to tutoring have an important effect on students' learning. However, limited research focuses on the effects of peer tutor approaches. More though conflicting evidence is present in the context of teacher-tutors. Pata, Sarapuu and Lehtinen (2005), defining an active and passive tutor style, suggest that an active and more controlling tutor seems to cause a negative influence on students' self-initiative. Other research (Rasku-Puttonen, Eteläpelto, Arvaja, & Häkkinen, 2003) reports however that students' self-regulation was stimulated in controlling environments where tutors took control and initiative. This study will investigate these somewhat conflicting results more into depth. More specific, the effects of two contrasting approaches to tutoring on students' self-regulation of learning and motivation will be investigated (RQ1). Furthermore, previous research in the context of workplace training indicates that self-efficacy moderates the effect of the training method on training outcomes (Saks, 1994). Since the general added value can be questioned, this study will look into the effects of the approach to tutoring taking into account different student profiles concerning their level of self-efficacy (RQ2).

Methodology

A quasi-experimental study was set up in a Medical faculty. Students from the second master year were supported by peer tutors in the preparation for their medical skills examination. Peer tutors with specific skill expertise were recruited from the third, fourth and fifth year and provided each eight hours of skills training. A number of peer tutors (n=16) was trained to approach their tutoring directive, others (n=17) to act facilitating. These two contrasting approaches were developed and defined based on a literature review (e.g. Roséé, Moore, VanLehn, & Albritton, 2001). While a directive tutor gave cut-and-dried answers and demonstrated skills, a facilitating tutor asked questions and stimulated students to think for themselves. The approach implementation was checked by video observations and the administration of a student questionnaire concerning their peer tutor. Students were randomly assigned to either the directive (n=102) or the facilitating (n=99) condition. To investigate the effects on students' learning, students administered on beforehand and at the end a questionnaire concerning their self-regulation of learning, self-efficacy (MSLQ: Pintrich & Garcia, 1991) and motivation (Vansteenkiste, Soenens, Sierens, Luyckx, & Lens, 2009). AN(C)OVA analyses were performed.

Results

ANOVA analyses showed no initial differences between the two conditions concerning the variables of interest. However, two differences were installed after the sessions. A first difference in self-regulation concerned the rehearsal behaviour of students, $F(1,196)=3.831$, p Three profile groups were created concerning students' level of initial self-efficacy: a low (x pct.75) group. The differences found in the general ANCOVA analyses only remained in the average self-efficacious group. Directive trained students with an average self-efficacy concerning the course reported a higher degree of rehearsal behaviour ($M=12.23$, $SD=2.82$), $F(1,92)=4.093$, p Conclusion This study suggests that the approach to tutoring affects to some degree students' learning. On the one hand, students from a directive tutor seemed to feel a greater need to rehearse while facilitative trained students could be hypothesised to experience a sufficient mastery or confidence concerning the subject matter. However, these latter students were less autonomously motivated despite the potential of this approach in fostering an autonomous motivation. However, it seems that the approach primarily matters for students with an average self-efficacy, although also low self-efficacious students benefitted more from one approach in particular, the facilitating approach. This study suggests that the best approach to tutoring does not exist. Student profiles should be taken into account. This study opens the discussion concerning the discrepancy between the actual practice where teachers and tutors are still directive steering the learning process and the pedagogically preferred practices where students are stimulated and inspired to create their own learning.

PAPER PRESENTATION

Enhancing text comprehension through TV viewing

Lucia Lumbelli, University of Trieste, Italy; Gisella Paoletti, University of Trieste, Italy; Maurizio Boscarol, Univ. of Trieste, Italy; Sara Rigutti, Univ. of Trieste, Italy

An educational approach aimed at enhancing reading comprehension and based on TV viewing was experimentally checked. Suggestions from studies on the importance of inference both in text and TV processing (Pezdek, 1987) and on animation in multimedia learning were applied to educational sessions focused on 6 episodes of the cartoon series *The Simpsons*. In particular, the use of pauses (Schnotz & Lowe 2008), and the activities of self-explaining (Hegarty et al. 2002) and recalling as learning strategies (Kombartzky et al. 2010) were applied to the TV passages in which connective inferences were required.

Two groups of 19 ninth graders were formed matched on reading comprehension ability. The experimental group was given 6 educational sessions of about one hour, each centered on one episode of *The Simpsons*. No special task was given to the control group. At the end of the 4-months experimental period, both groups were given a post-test, consisting of 30 multiple choice questions about 4 informative texts with pictures, designed and tried-out ($\alpha = 0,72$) to measure the ability to provide coherence (both within the text and between text and pictures) by drawing the inferences required. Comparison between the scores on this post-test proved the effectiveness of the educational intervention : $F(1,36) = 5.47682$, $p = 0.02493$. The feasibility of using amusing material to reach an important educational goal has thus been shown.

The investigation started from the following research question : can we enhance the ability to draw connective inferences in the comprehension of written text with static pictures through an educational task focused on viewing a TV program? precisely, a program with two features, (a) being amusing and (b) requiring many inferences necessary both to coherently organize the sequence of narrative events, and to fully understand the frequent gags and witty utterances?

The prediction of the feasibility and effectiveness of such an educational approach is based on a series of main premises deriving from different research fields.

Firstly, the ability to integrate explicit text information by making correct inferences is an important component of both reading comprehension and TV comprehension (Pezdek, 1987).

Secondly, while we agree with Schnotz & Lowe(2008) that the association of an educational task with amusement may be a source of cognitive flaws, we also assume with them that dynamic pictures have the potential for playing a motivational or affective role and that the educational task can be designed so as to counterbalance those flaws.

Thirdly, the perspective of this counterbalancing task can be also based on those analyses of the cognitive processes involved in animation that make it challenging for important operations of text comprehension. Because of the transitory, fleeting nature of animation, students cannot adequately monitor their own processing and their selection of information is more likely to be based on the visual prominence than on the cognitive significance (Lowe 2003, 2004, Schnotz & Lowe 2008). One of the consequences of the insufficient processing due to the above mentioned characteristics of dynamic pictures is the fact that the connective inferences which would provide coherence to text representation are less frequent in TV comprehension than in reading(Salomon, 1994; Lumbelli, 2008).

Our hypothesis is that the ability to connect information items with each other can be enhanced by (a) inviting students to watch successive segments of TV text, and recall and self-explain the outcome of their processing , and (b) encouraging them to complete their own verbal protocols and go on with the search through their memory. Precisely because a whole series of comprehension problems are likely to arise, students will be given just as many opportunities to face them and be helped to solve them.

The participants were two groups of 19 ninth -graders (the first year of an Italian secondary school) matched on the scores on a standardized test of reading comprehension ability. While the experimental group participated in the individual educational sessions which our intervention consisted of, the controls only took part in the ordinary classroom activity .

Here is a synthesis of the method adopted. The TV texts on which the sessions were focused had to satisfy two main conditions. On the one hand, they had to attract our young viewers , thereby ensuring sufficient motivation to process the information; on the other hand, they had to require that many inferences to be drawn to give coherence to the viewer's representations. Both conditions seemed to be satisfied by most episodes of the cartoon series The Simpsons. Six episodes were selected and analyzed to identify the most important passages where inference is needed to restore local and global coherence. Pauses were introduced immediately after each of these . During these pauses (2 or 3 for each episode) the participants were asked to recall what they had just watched and heard. Completion and clarification of the spontaneous verbal protocols have been encouraged by a feedback consisting of mirroring those passages which appeared to require integration (Lumbelli, 1996). This special feedback has been shown to facilitate further search through a participant's memory and self-revision of initial protocols without interfering with autonomous mental activity. This procedure can be considered as an example of 'the principled design of learning strategies' (Kombartzky et al. 2010) ; in this case, what has to be learned is a correct monitoring of the inferences drawn when processing a text. In fact, recalling, paraphrasing, summarizing(Dansereau et al. 1979; Huk & Ludwigs 2009) and self-explaining (Hegarty et al. 2002;Lowe 2004) are considered as learning strategies.

The 6 educational sessions lasted about one hour and were carried out over a period of 4 months. Each session was audio-recorded.

In the post-test session, the ability to comprehend texts with static pictures was measured. The test consisted of 30 multiple choice questions referring to 4 informative texts that asked the students to draw inferences both to connect verbal items with each other, and verbal items with visual ones. An initial version of 34 questions was tried out and examined by item analysis, and 4 questions were eliminated to obtain an acceptable value of alpha (0.72).

The experimental group obtained mean score of 23.1(SD 2.7) while the control group's score was 20.3 (SD 4.4). The computation of ANOVA showed that the difference between the two means was statistically significant: $F(1,36) = 5.47682$; $p = .002493$. This outcome can be considered as a first confirmation of our prediction that the ability to comprehend a written text with static pictures can be improved by means of an educational treatment centered on

the experience of TV watching, accompanied by indirect encouragement to increase the mental effort invested in the processing.

Our educational experiment seems to have proved that research both about learning with animation and TV watching can help us solve the crucial question of combining cognition and motivation in instruction aimed at improving reading comprehension, such an important ability in almost all school activities.

PAPER PRESENTATION

How implementation intentions in multimedia learning can improve the use of learning strategies

Kim Colin Stalbovs, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

Successful learning with text and pictures requires learners to actively process both information sources. This can be achieved by the application of appropriate learning strategies. However, the self-regulated use of such strategies is demanding. Therefore, a promising means to help learners use learning strategies may be implementation intentions. Implementation intentions are "if-then" plans that strongly link opportunities for applying learning strategies to the actual act of carrying out such strategies. In order to investigate the effects of implementation intentions on learning outcomes, a first study was conducted comparing two groups who learned either with or without implementation intentions. Task interest was included as a factor. A significant interaction between implementation intentions and task interest showed that especially less interested learners benefited from implementation intentions, indicating that implementation intentions facilitate learning of learners with less suitable learner characteristics in particular. A second study, which is currently being conducted, investigates how implementation intentions should be phrased and used in an optimal way. The number of implementation intentions as well as the type of evoked strategy is varied. Learners either learn with one or three implementation intentions. With regard to types of strategy whose use is supported, the implementation intentions either evoke the use of text, picture, or integration strategies. Additionally, there is a group with mixed strategies and a control group without implementation intention. Learning outcomes are assessed; in addition, eye-tracking serves as an online measure of strategy use. Results of both studies will be presented at the conference.

Learning with multimedia (i.e., text and pictures) yields better comprehension than learning with text alone (Mayer, 2009). A prerequisite for this effect to emerge, however, is that learners actively process both representations. Active processing can be achieved by the application of cognitive strategies (Weinstein & Mayer, 1986). Within the Cognitive Theory of Multimedia Learning (Mayer, 2009) cognitive strategies pertain to the selection, organization, and integration of information from both text and picture (Kombartzky, Plötzner, Schlag & Metz, 2010). However, certain challenges are associated with the use of cognitive strategies. Not only do learners need to know what to do, they also have to know when to act. Furthermore, the self-regulated use of strategies requires cognitive resources and can easily overwhelm novice learners (Van Merriënboer & Sluijsmans, 2009). Only when strategy use is automatized, less cognitive resources are required. Hence, measures to improve the use of strategies should support the automatization of strategy use. Based on these requirements, we suggest the use of implementation intentions. Implementation intentions are a well-researched concept in motivational psychology (Gollwitzer & Sheeran, 2006). These "if-then" plans strongly link a situation that is favorable to achieve a goal to effective behavioral responses for attaining the goal (e.g., "After I have read a sentence, I will search the picture for the contents described therein!"). The formation of implementation intentions thus delegates behavioral control from the self to specific situational circumstances, creating very effective "instant habits". Not only do implementation intentions contain information about what to do and when to act, actions evoked by implementation intentions also share similarities with automatized actions. Study 1 In a first study, we tested the hypothesis that implementation intentions support the use of cognitive strategies in multimedia learning, thereby improving learning outcomes. Furthermore, based on prior research, motivation to learn was hypothesized to play an important albeit ambiguous moderating role: Either implementation intentions might be more effective for highly motivated learners (cf. Koestner, Lekes, Powers, & Chicoine, 2002) or they might show a compensatory effect and help especially those who are less motivated regarding the task at hand (cf. Orbell & Sheeran, 2000).

Method

Sixty university students participated in this study. The study used a two-group experimental design with task interest—as measure for motivation to learn—acting as a continuous factor. Participants learned about the topic of cell division by means of an illustrated explanatory text. Before studying the materials, participants either internalized two pre-phrased implementation intentions about the use of strategies of text-picture integration, or they did not internalize any implementation intentions. After learning, participants' learning outcomes were assessed by a multiple-choice post-test, both recall and transfer. Results. Multiple regression analyses were conducted for recall and

transfer performance with implementation intentions, task interest, and the interaction of implementation intentions and task interest as predictors. To follow up on significant interactions, simple slope analyses were conducted. All reported significant results are at least significant at $p < .05$. For recall, there was no main effect for implementation intentions or for task interest. However, an interaction between both predictors indicated that implementation intentions positively influenced recall performance for learners with low task interest, while no effect was found for learners with high task interest. For transfer performance, we found no main effect for implementation intentions, but a main effect for task interest. Surprisingly, performance decreased with increased task interest. Furthermore, there was a significant interaction between both predictors; implementation intentions had a marginally positive effect for learners with low task interest, but no effect on learners with high task interest.

Discussion

Implementation intentions brought no overall advantage to learners. The pattern of results suggests, however, that implementation intentions significantly support less motivated learners. This result corresponds well with previous findings that implementation intentions have a strong compensatory effect, especially when the involved activities are unpleasant. Thus, implementation intentions are a promising support for those who are in need of help the most.

Study 2

In a second study, which is currently being conducted, we investigate how to optimize the content and use of implementation intentions for fostering strategy use in multimedia learning. The study uses a $2 \times 3 \times 2$ between-subject design, with number of concurrently used implementation intentions (1 vs. 3) and type of strategy specified in the "then" part (text comprehension vs. picture comprehension vs. integration) as factors. Additionally, there is a group that learns with three implementation intentions (one of each strategy type), and a control group without implementation intentions. We assume that the internalization of three implementation intentions leads to a more adaptive use of strategies. Furthermore, evoking a mix of strategies should yield better results than evoking only one type of strategy. In order to test whether strategy use mediates the effect of implementation intentions on learning outcomes, the second study measures strategy use online by means of eye-tracking data. The results will be discussed at the conference. Implementation intentions represent an efficient and easily implemented means of improving multimedia learning especially for learners with unfavorable learning characteristics. Thus, it shows promise as an intervention for a variety of educational settings and learning domains.

PAPER PRESENTATION

Getting a Clue: How Initially Attending to a Picture Fosters Learning from Subsequent Text

Alexander Eitel, Knowledge Media Research Center, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany; Anne Schueler, Knowledge Media Research Center, Germany

Previous research has shown that information about the gist (after 150ms) and the functioning (after 2sec) are rapidly extracted from an instructional picture and presumably represented as a mental scaffold in memory. When corresponding text is read afterwards, we assume that information from the text is added to this mental scaffold. Hence, mental model construction from and comprehension of subsequent text should profit from a brief initial glance at an instructional picture. Ninety-five students learned from a text that described the structure, the kinematics, and the underlying principles of pulley systems and in four out of five conditions from an additional picture of a pulley system. Students saw either the text only, the picture preceding the text for 150ms or 2sec, a self-paced presentation of the picture before the text, or the text and picture were shown simultaneously. Facilitation of mental model construction was measured by the time students took to read the text about the pulley system. Text comprehension was measured by verbal and pictorial questions about the kinematics and the underlying principles of

pulley systems. Results confirm our assumptions that compared to a text-only condition students spent less time reading the text about the pulley system, and had a better comprehension of the underlying principles of pulley systems when they saw the picture for 2sec prior to reading the corresponding text. Comprehension of the kinematics, however, did not profit from the short presentation of the picture before the text.

Theory

In the current study we were interested in whether students learn better from the short presentation of a picture before the corresponding text than from text only. In a prior study we investigated which information can be extracted from common instructional pictures (i.e., causal systems) after short presentation (Eitel, Scheiter, & Schýler, 2010). The results of this study showed that students were able to verify statements about the "gist" of instructional pictures (i.e., about their global theme) after 150ms already. Students were able to verify statements about the functioning of instructional pictures after 2 seconds presentation time. In the current experiment we investigated whether information about the gist (after 150ms) and/or about the functioning (after 2sec) from an instructional picture (of a pulley system) would help in learning from subsequent text. Castelhana and Henderson (2007) argue that a short presentation of a picture is sufficient to activate a mental scaffold of the picture's spatial structure. We hypothesize that information acquired from subsequently read text may be added to this mental scaffold. Presenting the instructional picture for 150ms and/or 2sec should hence lead to an integrated mental model from text and picture information. This integrated mental model should result in better comprehension than a mental model constructed from text only (Schnitz, 2002). Moreover, adding information acquired from subsequently read text to the initially acquired mental scaffold should be less demanding than constructing a spatial mental model from text only (Glenberg & Langston, 1992). This should be measurable in terms of shorter reading time when presenting the picture for 150ms and/or 2sec versus presenting text only.

Method

Ninety-five students learnt about pulley systems. They were randomly assigned to one of five conditions (see Figure 1): (a) text only, (b) a picture presented for 150 ms before the text (150ms-before), (c) a picture for 2 seconds before the text (2sec-before), (d) a picture for as long as they liked before the text (self-paced-before), or (e) text and picture simultaneously (simultaneous). The text described the spatial structure of the pulley system, and what happens when the rope is pulled (cf. Boucheix & Schneider, 2009). The picture of the pulley system was a simple line drawing in black-and-white. Reading was self-paced in all conditions. Comprehension was assessed with a verbal multiple choice test and a labelling test (pictorial). Results from both tests were merged in the analysis. We distinguished between comprehension of the underlying principles of pulley systems (e.g., each free pulley reduces weight to be lifted by half), and comprehension of the kinematics of the system (i.e., being able to mentally animate the pulley system; Hegarty, 1992). Eye movements during learning from text and picture were recorded.

Results

We conducted three univariate ANOVAs to test our hypotheses. All reported differences were significant at $p < .05$. Comprehension of kinematics differed among experimental conditions in that it was better in the simultaneous and in the self-paced-before condition than in the text-only condition. Moreover, it was better in the self-paced-before condition than in the 2sec-before and in the 150ms-before condition. There were no further differences. Reading time on text differed among experimental conditions in that it was shorter in all conditions containing text and picture compared to the text-only condition with the exception of the 150ms-before condition.

Discussion

Presenting the picture of a pulley system for 2 seconds before the text led to a better comprehension of the underlying principles of pulley systems, and to shorter reading time on the text than presenting text only. We explain this finding by assuming that students will rapidly acquire a mental scaffold about the spatial structure of the pulley system that can then be integrated with information extracted from subsequent text, leading to facilitated processing and better comprehension of subsequent text. Presenting the picture of the pulley system for 150ms most likely was too short for students to acquire a mental scaffold about the spatial structure of the system. Comprehension of the kinematics was fostered only when students could inspect the picture for as long as they wanted to. The longer students inspected the picture, the higher the probability that they did not only encode the structure of the pulley system, but also inferred its kinematics during inspection (Hegarty, 1992). A brief glance at the picture (i.e., for 150ms or 2sec), by contrast, probably did not lead to a mental model that represented the kinematics of the system in an accurate way. Analysis of students' drawings of their mental models as well as their eye fixation patterns during picture inspection will check for these assumptions. These data will be presented at the conference.

PAPER PRESENTATION

The Importance of Design in Learning from Diagrams

Marije van Amelsvoort, Tilburg University, Netherlands; Jan van der Meij, University of Twente, Netherlands; Anjo Anjewierden, University of Twente, Netherlands; Hans van der Meij, Twente University, Netherlands

An experiment was conducted to assess whether the design of a node-link diagram influences how people look at the diagram, and whether this in turn effects recall of the presented information. Four diagrams were created that contained the same information (on the development of babies in the first four months of their lives), but had a different lay out. The orientation of the arrows between chunks of information was either from left to right or top-down, and the organization of the information was either with months on the left and development categories on top or the other way around. 82 participants were asked to study one of these four diagrams for five minutes, and do a retention test. Eye movements were recorded to analyze participants viewing patterns. We found that participants mainly followed the development categories when reading the diagram. The effect was stronger when the arrows followed the categories. Participants performed better on the questions that were focused on categories than on the questions that focused on months, regardless of the condition they were in. We conclude that perceptual cues such as arrows guide learners' orientation, but that the conceptual information is more important for the order in which people learn.

Many scholars have argued that node-link diagrams are good for learning. They show text in boxes, with lines or arrows to relate these boxes. Node-link diagrams can facilitate learning by clarifying relationships and illustrating structure. Implied in their theoretical benefits is that diagrams support learning by their perceptual features, i.e., textual, spatial, and graphical elements that improve reading. In practice however, results have been equivocal. So far, learning scientists have largely ignored design characteristics of diagrams that may help or hinder learning. A meta-analysis on research into concept maps showed that they are better for learning than text, lists, and outlines, but did not reveal why this is the case (Nesbit & Adesope, 2006). In our study, we have systematically varied the design of a diagram without changing its content, to examine if and how perceptual cues influence learning. The perceptual cues we used were arrows between the nodes in the diagram. Although arrows can have different meanings, in our case they are presumed to direct learners in a specific reading order (e.g., Tversky, Zacks, Lee, & Heiser, 2000). To examine how learners processed the diagram, we used eye-tracking. With eye-tracking we could analyze in what order the diagram was read.

For the analysis we developed a technique to find sequences in the eye-tracking data. Since eye-tracking does not give and answer to why learners processed the diagram the way eye did, we combined eye-tracking with a retrospective interview. The goal of our study was to assess (1) whether perceptual cues in a diagram indeed guide students' reading behavior and (2) whether the way students read a diagram influences what they remember from its content. Four versions of a diagram showing babies' development were created. Content of the diagram was the same, but the layout was different. Arrows and boxes made the orientation of the diagram to be either from left to right or top-down, and the development categories were on the left while the months were on top, or the other way around (see Figure 1). Example of one of the lay-outs; orientation on categories from left to right - Eighty-two university students were randomly assigned to one of the diagrams and asked to study it for five minutes. Their eye-movements were recorded. A post-test was administered to test how much participants remembered from the content of the diagram. Half of the questions required an orientation on months and the other half required an orientation on developmental categories. We also asked them to indicate how they studied the diagram and explain why they studied it the way they indicated. For the analyses, the diagram was divided into 24 look zones, one for each cell, and further divided in heading cells and body cells. We developed a model to investigate the order in which participants studied the diagram. The model tries to find sequences of minimally three look zones in the diagram body from left to right and

top-down. As long as the time spent in a look zone belonging to the sequence is larger than twice the time spent in a look zone not fitting the sequence, the sequence is intact. A repeated measures ANOVA showed an interaction effect between condition and time in sequence for left to right compared to top-down, $F(3,78) = 32.33$, p partial $\eta^2 = 0.55$. In all conditions time in sequence for the headers was longer for the category headers compared to the month headers. These data show that when the category headers were on top, participants read longer top-down, while when the category headers were on the left, participants read longer from left to right. The effect was stronger when the arrows followed the categories. By analyzing the first sequence of each participant we found that most participants initially followed the arrows. This is consistent with participants' own account of how they initially studied the diagram, except for the condition where the arrows followed the months top-down (Table 1). Table 1. Number and percentage of participants who initially followed the perceptual cues based on eye-tracking data (left) and participants' own account (right).

Overall, participants answered about half of the post-test questions correctly, with a mean of 7.35 (SD = 2.96) out of 16 points. A paired-samples t-test showed that participants more often gave right answers on the questions focused on categories, $M = 4.14$, $SD = 1.79$, than on the questions focused on months, $M = 3.21$, $SD = 1.58$, $t(81) = 5.16$, $p F(1,81) = 0.09$, $p = 0.97$ and $F(3,81) = 0.42$, $p = 0.74$ respectively. Diagrams for learning promise to guide a learner through the information with perceptual cues. In our study, perceptual cues were arrows intended to guide the learners to read a diagram in a certain order. We found, however, that the arrows were hardly followed when studying the diagram. Most participants made their choice for reading order by looking at the content of the headers. Only in the initial stage participants followed the arrows.

Our results imply that in designing learning material, we cannot simply assume that learners will follow the design elements and that the perceptual features do not necessarily impact students' learning. PAPER PRESENTATION

Statistical problem solving with external representations

Stephanie Lem, K.U.Leuven, Belgium; Patrick Onghena, K.U.Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium; Wim Van Dooren, K.U. Leuven, Belgium

Being able to reason about distributions of data is considered to be an important outcome of statistics education. In order to be able to reason about distributions, one must be able to interpret external representations for data distributions. Research did already provide some anecdotal evidence on the occurrence of misinterpretations of these representations by students, but no research has thus far focused on the role of external representations in distributional reasoning. In this study we systematically varied the representation that accompanied a task between participants. Following a cognitive fit approach, we searched for matches between tasks and representations. Depending on the task, some representations led to better achievement than other representations. However, because of the low overall accuracy rates and various difficulties that students showed in interpreting these representations, strong cautiousness in making claims about matches between tasks and representations seems to be warranted.

Understanding distributions of statistical data is considered to be an important outcome of statistics education and a prerequisite for understanding more complex theoretical and sampling distributions (Meletiou & Lee, 2002). As data distributions are only accessible by means of external representations, understanding these representations is an important skill students have to acquire in a statistics course. Some anecdotal evidence shows nevertheless that students have great difficulties interpreting especially box plots and histograms (e.g., Bakker, Biehler, & Konold, 2004; delMas, Garfield, & Ooms, 2005). More systematic research is however still necessary to learn more about the role of external representations in distributional reasoning.

In this study we systematically varied representations between participants in order to study the role of external representations in distributional reasoning. By taking a cognitive fit perspective we tried to find matches between certain tasks and certain representations. The cognitive fit theory (Vessey, 1991) states that problem solving is facilitated when the information emphasized in the external representation, in the task, and hence in the cognitive

processes, match, leading to a consistent mental representation of the problem at hand. This way the chances of finding a correct solution to the problem are maximized, because task and representation match, resulting in a 'cognitive fit'.

Method

167 first year university students of educational sciences participated in return for course credit. Prior to their participation they had all completed the same introductory statistics course that covered all topics that were part of our test.

The paper-and-pencil test consisted of eight items in which students had to compare the distribution of the life span of batteries of two brands with respect to the mean, the median, the skewness, or the variation. Half of the items were about two symmetrical distributions, while the other half were about a symmetrical and an asymmetrical distribution. The representation that accompanied the tasks was randomly varied between participants: either a dot plot, a grouped histogram, a box plot, or a list of descriptive statistics. The items had a multiple-choice format, but also asked the students to explain how they arrived at their response.

Results

Overall, 58 % of all responses were correct. Using a generalized linear mixed model with correctness of response as the dependent variable, we found a main effect of task, $F(7, 1129) = 21.35$, $p < .001$, $F(3, 1129) = 11.75$, $p < .001$, $F(21, 1129) = 2.78$, $p < .001$. Table 1 shows the percentages of correct responses per item and representation. The results of the logistic regression analyses per task show four main effects of representation. (Table 1 about here)

In this table we see that the matches between tasks and representations we would make based on the percentages of correct responses would frequently be based on low accuracy rates, rather than on high accuracy rates with a certain representation. This suggests that these representations do not lead to a cognitive fit with the specific tasks, and/or that students are not able to interpret the representations correctly.

A look at the explanations students provided for their erroneous responses reveals that indeed students very often misinterpret these representations. On top of that, 37% of the correct responses were also accompanied by an incorrect explanation. All erroneous explanations were systematically analyzed. Examples of misinterpretations are: Comparing the height differences of the bars in histograms in order to compare the variation of two histograms and interpreting the area of the box of a box plot as representing frequency or proportion of observations.

Discussion

Our results show that students' fluency with the studied representations is relatively low, which is mainly caused by some systematically occurring misinterpretations. Based on these results, it would be inappropriate to make claims about matches between representations and tasks.

Our results have several implications for research. First, when studying students' distributional reasoning, it is important to take the representation used to present students with tasks into account, as a representation can have a significant effect on students' reasoning. Second, it is clear that not only characteristics of the task and representation should be taken into account when looking for matches between tasks and representations; also other factors such as context and representational fluency of the problem solver are likely to influence these matches. Third, several new research questions arise, such as: Which subject characteristics influence the match between task and representation? And where do the misinterpretations that students hold against representations for data distributions come from?

For education these results show the importance of being fluent in the use of these representations. Education should hence pay more attention to the interpretation of these representations. Furthermore, the specific misinterpretations we found can help teachers diagnose, prevent, and remediate these misinterpretations.

PAPER PRESENTATION

Assessing the relationship between Piagetian operations, calculations and arithmetic problem-solving

Jose I. Navarro-Guzman, University of Cadiz, Spain; Manuel Aguilar-Villagran, University of Cadiz, Spain; Esperanza Marchena, University of Cadiz, Spain; Gonzalo Ruiz Cagigas, Universidad de Cadiz, Spain; Inmaculada Menacho, University of Cadiz, Spain; Estivaliz Aragon, University of Cadiz, Spain; Candida Delgado, University of Cadiz, Spain

The main target was to study the relationship between logical competences and addition, subtraction and verbal arithmetic problem-solving. Logical competences were assessed by the Piagetian test but using numerical contents. The TEDI-MATH test (Grêgoire, Noël, & Van Nieuwenhoven, 2005) was used. TEDI-MATH assesses several numerical

competences (counting skills, numbering, transcoding, Base-10 comprehension, arithmetic, quantity estimation). 122 first grade primary school children (61 boys and 61 girls) average age 6.11, from Cadiz (Spain) school district were evaluated. Participants were evaluated at the end of the first academic year (June 2006). The operational tests were number seriation, classification, number conservation, number inclusion and additive decomposition. Arithmetic skills were evaluated with different items: addition, gap addition, subtraction, gap subtraction, arithmetic total score and arithmetic problem-solving. Results show that participants with high scores in logical tests also got high scores in arithmetic, even if items were presented in classical or verbal style. Seriation and addition decomposition tests rather than classification better discriminated experts and non-expert participants. Data suggests validity using logical operation testing in order to assess mathematics development and diagnose Mathematics Learning Disabilities.

The influence of Piaget's model in number sense development has been very important in teaching and learning early mathematics. This model has also been useful in understanding Mathematics Learning Disabilities (Dyscalculia). From this point of view, Dyscalculia is the result of a lack of development of logical operations supporting number sense. As, according to Piaget, the level of logical development in children shapes a structure, then the assessment and treatment of Dyscalculia would be based on multiple contents that support logical operations. However, Piaget's model has been criticized from different perspectives. One of the most important considers that children do not all develop in the same way. Different studies using extensive samples have shown great variability in operational development. Those studies consider that Piaget's stages do not appropriately describe developmental psychology, and make it difficult to assess operational level with a small number of tests. Considering this position, operational assessment following Piaget's model is just an evaluation of a small number of mental operations and certain contents. No general inferences can be made from a simple operational assessment. Another criticism of Piaget's model is related to the factors linked with children's answers to the tests. Interaction with adults, language used and the size of comparative groups have all been considered to influence children's answers to Piaget's tests. Considering this and after analyzing experimental data, some authors have doubts about Piaget's operational model of number. They consider it to be incomplete and inadequate in addressing the development of children's numerical skills. Piaget under-estimated the role of language and counting as Gelman, & Baillargeon (1983) have elucidated. Despite these different perspectives, other authors consider that Piaget's model is still useful. A completed conceptualization of number necessarily infers logical functions and/or interaction between counting skills and logical capability (Lehalle, 2002; Van Luit, 1998). The logical capability defended by Piaget does not imply that, before logical operation acquisition, number does not have any sense for children, nor that their arithmetic skills are nil. (Grégoire, 2005). Gregory (2005) also remarks that if the main target is to assess logical skill acquisition involved in number comprehension, operational tests should be based on numerical items, minimizing non-numerical items when operational assessment is carried out. Following these rules should improve operational test validity in number contexts and give results more in accordance with Piaget's model.

Method

Taking the previous ideas as our starting point, a comparative study was designed. The main target was to study the relationship between logical competences and addition, subtraction and verbal arithmetic problem-solving. Logical competences were assessed by the Piagetian test but using numerical contents. The TEDI-MATH test (Grégoire, Noël, & Van Nieuwenhoven, 2005) was used. TEDI-MATH assesses several numerical competences (counting skills, numbering, transcoding, Base-10 comprehension, arithmetic, quantity estimation). 122 first grade primary school children (61 boys and 61 girls) average age 6.11, from Cadiz (Spain) school district were evaluated. Participants were evaluated at the end of the first academic year (June 2006). The operational tests were number seriation, classification, number conservation, number inclusion and additive decomposition. Arithmetic skills were evaluated with different items: addition, gap addition, subtraction, gap subtraction, arithmetic total score and arithmetic problem-solving.

Results and discussion

Considering the logical operations data, differences between expert and non-expert participants can be established (table 1)

Logical operations	Experts	Non-Experts
Number seriation	100	22
Classification	18	104
Number conservation	42	80
Number inclusion	21	101
Addition decomposition	25	97

Number seriation was the easiest logical operation acquired by children. Classification was the most difficult. Data indicated that first grade children still need a long time for logical operation acquisition. And probably a new assessment at the end of the second grade year would have very different results. Using the previous data, participants were assigned to 2 groups, according to their logical operation skills. Then the arithmetic performance for both groups was compared. Results show that participants with high scores in logical tests also got high scores in arithmetic, even if items were presented in classical or verbal style. Seriation and addition decomposition tests rather than classification better discriminated experts and non-expert participants. Data suggests validity using logical operation testing in order to assess mathematics development and diagnose Mathematics Learning Disabilities.

Implications for the theoretical context

This research brings together knowledge from Science Education, Cognitive Psychology and Early Mathematic Learning. It also has an added value validating the measurement of cognitive skills involved in Mathematical Learning. Both should result in the early diagnosis and identification of children with Mathematics Learning Disabilities and a subsequent improvement in their school performance. Results would stress how important to implement specific learning programs is in order to build up the Math performing Spanish range in PISA report.

PAPER PRESENTATION

Abstract and concrete examples in learning math-Replicating and elaborating Kaminski et al.'s study

Dirk De Bock, Hogeschool-Universiteit Brussel, Belgium; Johan Deprez, Universiteit Antwerpen, Belgium; Wim Van Dooren, K.U. Leuven, Belgium; Michel Roelens, Katholieke Hogeschool Limburg, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Kaminski, Sloutsky, and Heckler (2008) published a study on "The advantage of abstract examples in learning math" in *Science* in which they claim that students may benefit more from learning mathematics through a single abstract, symbolic representation than from multiple concrete examples. In their central experiment, participants learned either an abstract (or "generic") instantiation of a mathematical concept, or one or more concrete instantiations of that concept. This publication called forth both enthusiastic and critical comments by mathematicians, mathematics educators and policy makers worldwide. Basic elements of critique refer to the unfairness of Kaminski et al.'s comparison due to the role of uncontrolled variables, which poses a threat to the generalizability of their results. But, as far as we know, no attempts have been undertaken yet to test these critiques empirically. We report an empirical study that involves a partial replication but also an important extension and validation of this widely noticed study. Our quantitative results confirm the findings of Kaminski et al., but our qualitative data raise serious questions about their interpretation of what students actually learned of the abstract concept exemplification. Moreover, whereas Kaminski et al. showed that abstract learners transferred what they had learned into a similar abstract context, through our extended design, we were able to show also that students who learned from concrete examples transferred their knowledge into a similar concrete context. In light of these new findings, the generalizability of Kaminski et al.'s results and their basic claim about learning mathematics are reviewed.

Theoretical and empirical background

Most mathematics educators nowadays take more or less for granted that mathematics should be taught "from concrete to abstract" and that a series of well-chosen examples (and counterexamples) can facilitate students' understanding of an underlying or more general mathematical idea. Recently, this point of view was explicitly questioned. In *Science*, Kaminski, Sloutsky, and Heckler (2008) published a study on "(t)he advantage of abstract examples in learning math" in which they claim that students may benefit more from learning mathematics through a single abstract, symbolic representation than from multiple concrete examples. In their central experiment, participants learned either an abstract (or "generic") instantiation of a mathematical concept, or one or more concrete instantiations of that concept. The publication in *Science* called forth both enthusiastic and critical comments by mathematicians, mathematics educators and policy makers worldwide. Basic elements of critique refer to the unfairness of Kaminski et al.'s comparison due to the role of uncontrolled variables and the content validity of the instrument, which poses a threat to the generalizability of their results. But, as far as we know, no attempts have been undertaken yet to empirically substantiate these critiques.

Aims

We elaborate on two main elements of critique and we provide empirical evidence to substantiate them. First, we argue for why the comparison made by Kaminski et al. is basically unfair. Second we query about what the students actually learned from the abstract examples. To support these two elements of critique empirically we set up a replication and extension study.

Method

One hundred and thirty undergraduate students in educational sciences participated in a study with two phases: (1) training and testing in a learning domain, and (2) testing for transfer. All participants were randomly assigned to one of four experimental conditions – AA, AC, CA, and CC – in which the first letter specifies the learning domain and the second one the transfer domain, both of which could be either abstract (A) or concrete (C). The AA- and CA-conditions were used in Kaminski et al.'s experiments; the AC- and CC-conditions were important additions by us in order to measure transfer to a new concrete domain. The A-domains were operationalized by a context using arbitrary symbols and their combination rules. For the C-domains, a modulo 3 addition context with physical referent was developed. In the four experimental conditions, the test at the end of the learning phase as well as the transfer tests consisted of 24 multiple-choice questions.

As second important difference with Kaminski et al.'s procedure – besides adding two conditions –, we included a single open question immediately after the learning phase in order to qualitatively investigate what students actually learned of the abstract or concrete examples, something that was not investigated at all by Kaminski et al.

Training and testing happened individually on a computer screen and the two phases immediately followed after each other. Participants proceeded through training and testing at their own pace. Participants' learning and transfer test scores were analyzed using two single-factor ANOVA's. To analyze participants' explanations for their answers on the open question, a scoring system was developed and applied to all participants' explanations by two independent raters.

Results

Our results with respect to the two conditions that were taken from Kaminski et al.'s original study confirm their findings: The AA-group outperformed the CA-group on the abstract transfer task ($p < 0.001$). So if transfer in a new abstract domain is targeted, abstract instantiations are more advantageous than concrete instantiations. However, through our extended design, we were able to show that the opposite holds too: CC-group outperformed the AC-group on the concrete transfer task ($p = 0.044$). So, transfer to a new concrete domain is more enhanced by a concrete learning domain than by an abstract one.

The analysis of participants' explanations on the open question after learning in the abstract learning domain provided little or no evidence that these participants learned the quintessence of the abstract concept that was aimed at in the intervention: Although participants were asked to explain as precisely as possible how they had found their answer, they rarely used the intended concepts in their explanations. On the contrary, a vast majority of participants just repeated specific rules – suggesting that they merely learned them by heart – or referred to a very different mathematical concept, i.e. addition modulo 3.

Discussion

We replicated and elaborated Kaminski et al.'s widely noticed study and re-examined their claim that students may benefit more from learning mathematics through a single abstract, symbolic representation than from multiple concrete examples of a to-be-learned concept. Our results confirm the basic finding by Kaminski et al.: Transfer in a new abstract domain is enhanced by abstract rather than by concrete instantiations. But, whereas Kaminski et al. showed that abstract learners transferred what they had learned into a similar abstract context, through our extended design, we were able to show also that students who learned from concrete examples transferred their knowledge into a similar concrete context. Moreover, our qualitative data raise questions about their interpretation of what students actually learned of the abstract examples. These results pose a serious challenge to Kaminski et al.'s affirmative conclusions about "(t)he advantage of abstract examples in learning math".

Kaminski et al.'s original study boosted the public debate on how mathematics should be taught and learned. However, for several reasons, we think it is inappropriate to already extrapolate Kaminski et al.'s – and, thus, also our – findings to the broader realm of mathematics education: The mathematical topic of both studies is a very particular one, the conducted short-term "laboratory" experiments differ on crucial points from that in typical educational settings, and their effects over longer periods of time remain unexplored.

PAPER PRESENTATION

Increasing freshmen's responsibility for learning in Web-based courses: Advantages and challenges

Ornit Sagy, Technion, Israel; Yael Kali, Technion, Israel; Masha Tsaushu, Technion, Israel; Tali Tal, Technion, Israel; Dan Zilberstein, Technion, Israel; Shimon Gepstein, Technion, Israel

Instruction in large higher-education introductory courses is usually based on lectures. Research shows that such instruction fails to help students develop conceptual understanding because it does not encourage them to take responsibility of their own learning. In this research we developed an instructional model that harnesses technology to support students in assuming responsibility of their own learning, and gradually implemented this model in a large introductory biology course. We examined how the gradual shift of responsibility from the instructor to the students affected their self-regulation and self-efficacy. Verbal analysis of students' utterances revealed that students felt a sense of confidence when all course contents were provided to them both in the lectures and in an online tutorial, this confidence encouraged them to take responsibility of their own learning. However, when students knew that they have to rely on their self-learning from the tutorial for some of the course material, they were reluctant from taking that same responsibility. We conclude that it is imperative to provide appropriate supports that will induce a critical level of comfort and confidence that will enable students to take higher responsibilities of their learning.

Introduction

In many universities across the world, introductory courses are huge, constraining the teaching mainly to lectures. Research shows that such instruction fails to help students develop conceptual understanding because it does not encourage them to take responsibility of their own learning (McCray et al., 2003).

The literature refers to two related entities that enable learners to take such responsibility: Self-regulated learning, and Self-efficacy. Zimmerman (1998) describes self-regulated learning as a self-directed process (including thoughts, feelings and actions) that a learner uses in order to attain a personal goal of learning. He claims that it's a cyclical process with three phases: Forethought, Performance-Control and Self-Reflection. Self-efficacy, on the other hand, is described as one's belief in his/her capability to produce at a designated level of performance and to influence the process of getting to that level (Bandura, 1994).

In this research we developed an instructional model that harnesses technology to support students in assuming responsibility of their own learning gradually, and implemented it in a large introductory biology course. In phase-1 of the study, we introduced an online tutorial (including videotaped lectures, interactive visualizations and self feedback) which usage was optional while the lectures covered all course contents. In phase-2, students were required to self-learn some contents, so that the lecturer could focus on more complicated topics. The purpose of the research was to examine if the gradual shift of responsibility from the instructor to the students affects their self-regulation and self-efficacy.

Methods

834 freshmen biology students participated in the study over 3 semesters (2008-2010).

Data sources were: (a) students' free comments from a feedback survey given toward the end of the course, (b) protocols of interviews with 18 selected students (c) server logs which provided information regarding the usage of the tutorial, (d) final exam scores.

Students' survey utterances were analyzed using verbal analysis (Chi, 1997), with the categories shown in Table 1.

Table 1: Verbal analysis categories

Findings and Discussion

Use of the online tutorial, satisfaction and test scores. Once the tutorial was introduced (phase-1) its usage was high (used by more than 90% of students). The usage became even more extensive in phase-2. For example: the average number of different video lectures watched per student rose from eight to eighteen. Students' satisfaction from the tutorial is evident from the survey results: 80% of the utterances regarding the tutorial were positive. No difference was found in the final exam scores, indicating the students' ability to cope with the self-learning requirement.

Self-regulation and self-efficacy

Analysis of student survey answers showed a rise in three indicators in phase-1 (Intrinsic interest, Mastery experience and Emotional state), and then a drop in phase-2 (Figure 1). However, Strategic planning constantly decreased (Figure 2) as students were required to take more responsibility of their learning.

Figure-1: Rise and drop in positive self-regulation and self-efficacy indicators

Figure-2: Strategic planning utterances

We interpret the rise and drop in Figure-1 in terms of Maslow's hierarchy of needs theory (1943). We view the rise between the pre-intervention and phase-1 as an indication of a sense of confidence that students felt when all course contents were provided to them both in the lectures and in the online tutorial (Student: "I always prefer to rely more on the lectures. But there is like self confidence ... a good feeling that you can't miss anything... there's always the website"). Building on Maslow's theory, we believe that this confidence provided students with an environment comfortable enough to expand their self-interest. However, in phase-2, students knew that not all contents are covered in lectures, their sense of confidence was shattered, and their psychological resources were directed towards more basic needs (making sure they learn everything they should know for the test). Thus their interest in expanding their horizons decreased.

We believe that the drop in strategic planning (Figure 2) results from a gap between students' theoretical aspiration to be provided with a variety of learning resources, and their actual desire to be taught via lectures. When students thought hypothetically about improving the course they suggested additional learning resources "A video-taped lecture will help for sure... more copies of the textbook in libraries..." However, once additional tools were provided, and especially when students were required to use them, they restrained from taking more responsibility of their learning. It seems that students prefer to keep their comfort zone in a situation in which the instructor has the responsibility for making all the strategic planning.

Theoretical and Educational Significance and Implications

This study shows that indeed, use of technology can encourage self-regulated learning and support self-efficacy. However, when using technology to do so, it is imperative to provide appropriate supports that will induce a critical level of comfort and confidence that will enable students to take higher responsibilities of their learning. We believe that the drop in self-efficacy and self-regulation components in phase-2 resulted from transferring only partial responsibility to the learner. We have evidence showing that students were confused. Based on Maslow's theory (1943) it seems that phase-2 students were not provided with enough support that would give them confidence that they can succeed. That said, we would like to stress that we are not backing away from our goal to increase students' responsibility of their own learning, rather, we stress the importance of providing them with the appropriate support in doing so.

PAPER PRESENTATION

The use of videoconference in online education and its effect on student performance

Bas Giesbers, Maastricht University, Netherlands; Bart Rienties, University of Surrey, United Kingdom; Dirk Tempelaar, Maastricht University , Netherlands; Wim Gijselaers, Maastricht University, Netherlands; Mien Segers, Maastricht University, Netherlands

Synchronous communication is superior to asynchronous communication in establishing discourse due to the ability to express immediate feedback (e.g. via chat), the ability to use voice and intonation and to show body language (e.g. via videoconferencing). However, research has shown that just using social media not necessarily has the desired effect

(e.g. increased performance). This may be explained by the pedagogical model used or by personal characteristics of the student. This contribution focuses on the relationship between learning performance, the choice of communication tools and the influence of personal characteristics motivation and learning style on these. Initial analysis shows there are relationships though further analysis like multilevel analysis is required to gain further insight first in the effect of belonging to a certain tutor group and second in the interaction effects of different elements of our model.

Synchronous communication (like chat and videoconferencing) is superior to asynchronous communication (like discussion forums) in establishing discourse due to the ability to express immediate feedback (chat), the ability to use voice and intonation and to show body language (videoconferencing) (Beers, Boshuizen, Kirschner, & Gijssels, 2007; Derks, Bos, & Grumbkow, 2007; Haythornthwaite, 2000; Tu, 2002; Tu & McIsaac, 2002). It is generally assumed that synchronous communication might reduce meaning barriers, the obstruction of mutual construction of meaning of information from sender to receiver, when learners are working and learning together in an online classroom (Bromme, Hesse, & Spada, 2005; Rummel & Spada, 2005). The choice to incorporate social media that allow for synchronous communication thus seems logical when aiming for improvement in the performance of learners in an online setting. In addition, many tools nowadays are easily accessible for free or at a very low cost. However, research has shown that using social media alone for this purpose not always has the desired effect (Lou, Bernard, & Abrami, 2006). Several factors help to explain why of which the first is pedagogy. In an extensive meta-analysis comparing asynchronous and synchronous communication in undergraduate online learning, Lou et al. (2006) follow Clark (1994) in his conclusion that the pedagogical model used is of higher influence on learning than the social media used. The pedagogical model underlying the online classroom in this contribution is Problem Based Learning (PBL) which is founded on generally accepted characteristics for effective learning like active learning, structured cognitive interaction and instructor guidance and has proven to be effective (Schmidt, Van Der Molen, Te Winkel, & Wijnen, 2009). Therefore, the pedagogical model in itself will not be the main focus of our study. Personal characteristics of a learner constitute the second factor. Among different personal characteristics that have been found to have an influence on student learning, motivation and learning style are probably the most extensively researched and both have been found to affect students' performance and the choices they make during the learning process (Järvelä, Volet, & Järvenoja, 2010; Vermetten, Lodewijks, & Vermunt, 2001). For this contribution we will focus on individual academic motivation from the perspective of self-determination (Ryan & Deci, 2000). Learning style is defined by Vermunt & Vermetten (2004) as a concept that encompasses a learners' conception of learning and learning orientation, the preference for cognitive and affective processing of content and his or her metacognitive regulation strategies. The present study focuses on the relationship between learning performance, the choice of communication tools and the influence of personal characteristics motivation and learning style on these. Students who attend more videoconferences and use more rich tools are expected to perform better than others. Further, we expect that students' choices to participate more actively, as defined by the number of web-videoconferences attended and the richness of communication tools used are mediated by motivation and learning style.

Method Setting

The present study took place in an online preparatory course in Economics for prospective bachelor students of an International Business degree program. This course bridges the gap in prior knowledge for prospective bachelor students. Students never met face-to-face prior to the course and could meet during the four weekly web-videoconferences that were offered (one hour each). Further communication took place via asynchronous discussion forums. The planned work load was 10 to 15 hours per week. Participants In total, 155 students participated in the preparatory course and were randomly assigned to 12 groups. The average number of members for each group was 14.08 (SD = 3.96). Their average age was 19 and 44% was female.

Instruments Performance measures

During the course, three progress tests and a final test were offered to students.

Academic Motivation Scale

The Academic Motivation Scale (AMS) was developed by Vallerand et al. (1992). The AMS consists of 28 items divided into seven subscales of which three concern intrinsic motivation, three subscales concern extrinsic motivation and the final scale concerns amotivation.

Inventory of Learning Styles

This instrument was developed by Vermunt (Vermunt & Vermetten, 2004) who distinguishes four domains or components of learning: cognitive processing strategies, metacognitive regulation strategies, learning conceptions or mental models of learning, and learning orientations.

Initial results

A one-way ANOVA to test for AMS differences based on the number of videoconferences participated in showed a significant difference between groups only on the Intrinsic motivation to accomplish subscale ($F(4,115) = 2.92$; p A one-way ANOVA to test for ILS differences did not show a significant difference between groups. A one-way ANOVA showed significant differences between groups on average progress test score ($F(4,164) = 41.69$; p Post-hoc tests showed that students who had participated in all four videoconferences on average scored significantly higher than all others on the progress tests. Performance of students who did not participate or participated once was significantly lower than performance of other students. Further, post-hoc tests showed the difference on final test scores between all groups to be significant except for the difference between group 0 and 1 and between group 3 and 4. Finally, post-hoc tests showed no significant difference on tool-use between groups of students who participated in the videoconference at least once.

Further analysis

The current analysis shows a relationship between videoconference use and performance and a weak relationship between motivation and videoconference use. However, drawing causal relationships and/or gaining insight in interaction effects require different methods to rule out error caused by selection effects for example. Also, subjects all were assigned to a tutor group which may further have influenced results as each group was tutored by a different tutor and developed its own social dynamics. Therefore, multilevel analysis will be performed to gain further insight first in the effect of belonging to a certain tutor group and second in the interaction effects of different elements of our model.

PAPER PRESENTATION

Orchestrating collaborative learning in a wiki-environment

Bram De Wever, Ghent University, Belgium

The present study investigates how activities should be orchestrated within a CSCL-environment in order to enhance students' collaboration. More specifically, in a wiki-environment the introduction of a collaboration script guiding students towards true collaboration and group work, instead of merely dividing the work and simply combining individual chunks of work, was studied.

First-year university students Educational Sciences taking the course Instructional Sciences ($N=262$) were asked to work intensively together in groups ($n=56$) of 5 during a two-week period in order to create a wiki documenting the use of peer assessment in education. All groups were required to develop a wiki containing several pages (overview, description, theoretical rationale, advantages, disadvantages, and points of attention) on peer assessment, based on 10 provided sources. Students were randomly assigned to groups and groups were randomly appointed to two conditions: 28 groups worked with a specific collaboration script (scripting condition) and 28 groups collaborated without the script (control condition).

The research question was whether the introduction of a collaboration script in the wiki-environment had a positive impact on students' actual collaboration. The results show that introducing a collaboration script actualizes that students (a) collaborate more instead of dividing the work, (b) get information out of more sources, (c) write on multiple parts/pages of the wiki, (d) read all the pages of the wiki, (e) feel that everyone is responsible for the complete wiki instead of one person per page, and (f) feel oneself responsible for the complete wiki instead of a single page. To conclude, the study shows an important impact scripting and concludes by discussing two critical elements, namely the time consuming nature and the risk of over-scripting.

Introduction

Within the field of computer-supported collaborative learning (CSCL), an important question is whether students are actively engaged and highly collaborating. In this respect, an important issue brought into attention by Larusson and Alterman (2009) is whether the "technology adequately support[s] the students' collaboration" (p. 371). The present study aims at taking this question one step further and investigates how activities should be orchestrated within a CSCL-environment in order to enhance students' collaboration. More specifically, the introduction of a collaboration script in a wiki-environment was studied.

Theoretical framework

The theoretical foundations for the design and implementation of CSCL-environments are generally based on the idea that knowledge is actively constructed by the learners (see e.g. Merrill, 1991). In this respect, sociocultural theorists draw on the insights of Vygotsky (1978), who argues that any higher mental function is first external and social before

it becomes internal. Therefore, they claim that knowledge is constructed through social interaction with others (see e.g. Duffy & Cunningham, 1996).

It is in this respect that the present study aims to guide students towards true collaboration and group work, instead of just dividing the work and merely combining individual chunks of work.

Method

Context & participants – The participants in this study were first-year university students Educational Sciences taking the course Instructional Sciences. Participation to the wiki-assignment was a complimentary part of the course. Students were divided in groups of 5. Due to non-participation (drop-out) one group consisted of 3 students and 16 groups consisted of 4 students. The other 39 groups consisted of 5 students. In total 262 students were divided over 56 groups.

Design – Students were asked to work intensively together during a two-week period in order to create a wiki documenting the use of peer assessment in education. All groups were required to develop a wiki containing several pages (overview, description, theoretical rationale, advantages, disadvantages, and points of attention) on peer assessment, based on 10 provided sources (10 research articles, of which 5 were labeled as main sources and 5 as additional sources). In addition, they were informed on the fact that it was allowed – and even appropriate – to look for additional sources.

Conditions – Two conditions were contrasted within this study: a scripting and a control condition. In the control condition, students were asked to look into the provided sources, the main sources being the most important ones, and to develop the wiki. In the scripted condition, students were requested to follow a specific script. First, they were informed that the step-by-step plan was meant to guide them and that it was to be seen as a flexible aid and not as a strict path. Next, the specific script was introduced. The script required students to read two sources and to start writing a draft of one part of the wiki. In this respect, the sources as well as the pages were divided among students, so that all students started reading different sources and started writing drafts for different pages. In succeeding steps, students had to read more sources and write and revise different parts of the wiki, until eventually everybody at least has read the main sources and rewritten all the parts. A detailed overview of this script is presented in Figure 1.

Figure 1: visual presentation of the script

Research question & hypotheses – The research question that drives this study focuses on whether the introduction of a collaboration script in the wiki-environment had a positive impact on students' collaboration. We hypothesized that the introduction of the collaboration script would actualize students to (a) collaborate more instead of dividing the work, (b) get information out of more sources, (c) write on multiple parts/pages of the wiki, (d) read all the pages of the wiki, (e) feel that everyone is responsible for the complete wiki instead of one person per page, and (f) feel themselves responsible for the complete wiki instead of a single page.

Results

Likert-scale (1-7) items were used to question students and gather data to check the hypotheses. The results are presented in Table 1.

Table 1: means for both conditions

Conclusion

The introduction of the collaboration script orchestrates the learning activities in the wiki-environment and lead students in the hypothesized direction of higher collaboration. However, a number of side effects will also be critically discussed in the presentation, more specifically the amount of time invested and the risk of over-scripting the learning activities.

PAPER PRESENTATION

Designing Online Interactive Environments with Animated Conversational Agents

Katerina Theodoridou, Centre for the Advancement of Research & Development in Educational Technology, Cyprus;
Charalambos Vrasidas, CARDET - University of Nicosia , Cyprus; Theano Yerasimou, Centre for the Advancement of Research & Development in Educational Technology, Cyprus

This paper presentation discusses findings from three research studies that involved the use of animated conversational agents for educational purposes. The agents were designed to present course-related material in university-level courses, and interact with the learners both in speech and in text form. The discussion revolves around findings pertaining to learning outcomes, as well as learners' perceptions and affective outcomes (interest, motivation, enjoyment) related to the agents' presence, image, interactivity, and humanness. The presentation concludes with guidelines that educators and instructional designers should consider when developing learning environments, in which agents are integrated. Findings from the studies and the relevant guidelines for designing such interactive environments contribute to the current literature as limited empirical research has addressed design indicators for effective online environments with animated conversational agents.

Aims

One of the latest products of the technological evolution with respect to virtual reality as a medium for enhancing education is animated conversational agents. They are software entities (avatars) supported by Artificial Intelligence engines, capable of displaying human-like characteristics while interacting with the learner in the form of speech and/or text.

The effectiveness of such agents in educational settings has been researched in various content areas in science, humanities, and education fields (Baylor & Ryu, 2003; Baylor, Shen, & Warren, 2004; Choi & Clark, 2006; Cole et al., 2003; Doering & Veletsianos, 2007; Doering, Veletsianos, & Yerasimou, 2008; Moreno, Mayer, Spires, & Lester, 2001; Theodoridou, 2009). Multiple studies have aimed at investigating the impact of agents on learning and affective outcomes, such as interest and motivation.

Up to this point however, empirical research findings are still rather inconclusive as to how agents should be incorporated in online learning environments so as to yield optimal learning and affective outcomes (Clark & Choi, 2005; Gulz, 2004). The purpose of this paper is to present guidelines that educators and instructional designers should consider when developing online learning environments, in which agents are integrated. These suggestions are based on three completed research studies conducted with university-level students that involved the use of animated conversational agents for educational purposes.

Methodology

This paper compiles the results from three empirical research studies, all of which were based on a mixed methods design.

The first study took place at a large research university in the Southwest United States, with 47 students enrolled in two fourth-semester Spanish courses; 24 participants belonged to the Control group (online environment with agent in audio) and 23 belonged to the Experimental group (online environment with agent in audio and image).

Quantitative data sources included: vocabulary pre-test, immediate and delayed post-tests, pre- and post-attitudes scale. Qualitative data sources included: open-ended questionnaire on learners' experiences in the environment.

The data collected from the pre-test and immediate and delayed post-tests were analyzed through descriptive statistics and a two-way repeated-measures ANOVA. The data collected from the pre- and post-attitudes scales were analyzed by using MANCOVA. The data collected from the open-ended questionnaire were analyzed in depth, based on the model of the Constant Comparative Method.

The second study involved 45 pre-service teachers enrolled in a blended teacher-education course at a large Midwestern university in the United States. Five different technology tools were incorporated within the course's online environment, and were utilized inside and outside of class based on the learners' needs. One of the tools was the agent, with which the learners were able to interact through synchronous conversation.

Quantitative data sources included learner questionnaires and qualitative data sources included learner-learner, learner-instructor, and learner-agent conversation and interaction data from the various technology tools. The data

collected from the learner questionnaires were analyzed through descriptive statistics, and the data collected through the conversations were analyzed using the Constant Comparative Method.

The third study involved 14 secondary education pre-service teachers enrolled in an online class at a large Midwestern university in the United States. Two online learning environments were available to the learners, both of which involved an intelligent system with which learners could converse. The first one had the agent only with audio and the second one had audio and the animated image of the agent.

Quantitative data sources included pre- and post- learner surveys and qualitative data sources included learner-agent conversations. The data collected from surveys were analyzed through descriptive statistics, while the data collected through the learner-agent conversations were analyzed through Computer-Mediated Discourse analysis.

Findings

In the first study, both groups yielded significant learning outcomes with respect to vocabulary recall and retention of new lexical items, but the ANOVA performed indicated no significant between-subject effect ($p = .935$). In regards to affective outcomes though, learners in the Experimental group expressed enthusiasm and attraction to the environment, indicating that they would definitely use the environment to complement their foreign language learning.

In the second study, learners indicated that the tools offering higher levels of interactivity, and in particular real-time interactions with the instructor and peers, were the most useful in: a) providing learners with support, b) advancing their motivation in completing the assignments, and c) intriguing them in further exploring other technologies and classroom integration practices. They indicated the agent as one of such tools offering high interactivity.

In the third study, a higher number of speech acts and conversations was recorded in the online environment with the agent's presence with the learners showing distinct preference for the specific environment due to the agent's humanness, friendliness and willingness to interact with the learners.

By examining the results obtained from all three studies and focusing specifically on the integration of the agents in the environments, some of the issues that emerge when it comes to designing effective environments of this sort are: the need for the agent to have an extensive knowledge base, accounting for the novelty effect of such a technology in the environment, providing for student autonomy and control with respect to the agent, emphasizing the humanness of the agent, giving the agent specific purpose, and developing structured and contextualized activities in the environment.

Theoretical and Educational Significance

In an era of continuing growth in the demand for online courses, it is important to design online environments that can provide to the learner even more than what the actual face-to-face environment can. Animated conversational agents have been proven to encourage and support learners during the learning process, while also increasing their motivation and enjoyment towards the course and the material. As a result, incorporating them in the online environment can reinforce the positive learning experience. However, for agents to be effective in the environment, some guidelines need to be followed. This paper combines results from three empirical studies in order to provide a list of such guidelines with the objective of adding to the current literature and providing recommendations so that the added pedagogical value of agents is utilized in online interactive learning environments.

PAPER PRESENTATION

Effects of role taking in on-line writing and reading activities in a blended University course

Donatella Cesareni, University of Rome, Italy; Stefano Cacciamani, University of Valle d'Aosta, Italy

Role taking has been often studied as an established technique used for educational activities. Educational researcher highlight that the possibility to play a specific role within the group in online forums leads students to greater responsibility to its own knowledge building activity other than towards the group itself. The present study focuses on participation in online activities, questioning if taking a role in a group leads to a higher level of participation and which role fosters more participation. 152 students, divided into 14 discussion groups, participated in a knowledge building activity in 3 modules lasting 5 weeks each. In each module students in turn took specific roles. We analyzed students participation in terms of both posted and read notes in knowledge building forums. We compared participation in the three different periods of two groups of students: students who took a role in the second period and students who didn't take a role at all. We used Module 1 as a pre-test and Module 3 as post test and we analyzed differences using T-Student test. Results evidence no differences in participation in Module 1 between the two groups, an higher participation of the group of students taking a role in Module 2, and this difference between the

two groups persists in Module 3. Students who had a role in Module 2 write and read more notes than students who didn't take a role also when none of them had particular roles.

Introduction

A relevant problem for the students in their first approach with the University is perceiving him/herself as an anonymous number in a large system, without a personal relationship with the teacher and sometimes also with other students. Many students feel then disoriented, without any guide about the strategies for an effective study activity. In this scenario it could be useful for the students to assume roles within work groups. In fact taking roles has been often studied as an established technique used for educational activities, mainly in terms of role playing activity. Resnick and Wilensky (1997), e.g., integrated role-playing activities into science and math classes and argue that role-playing can help students understand complex systems and relationships. Educational researchers have also investigated how role-playing in a digital environment fosters intrinsic motivation (Dickey, 2006). Despite this large interest, only few studies analyze the effect of students role taking in online and F2F activities in academic context (Spadaro, Sansone & Ligorio, 2009; Schellens, Van Keer & Valcke, 2006). These studies highlight that the assumption of a role leads the activity of individual students, providing them with a script in which to act, and regulates the interaction within the group. In addition the possibility to play a specific role within the group leads students to greater responsibility to its own knowledge building activity other than towards the group itself. To go in depth in this area of inquiry the present study focused on the following questions: 1) Does taking a role in a group in an on line course lead to a higher level of participation, in terms of writing and reading activity? And does the participation decrease, when the student end to take a role? 2) Which kind of role does foster a higher level of participation?

Method Participants

152 students (14 M, 138 F), attending the first year of the faculty of Psychology, University Sapienza of Rome, took part of this research. Procedure Students participated in a knowledge building activity in a blended course of Pedagogy, discussing online topics of the curriculum. Participants were distributed into discussion groups of 10-12 students. Online activities lasted the same period of the lectures and were divided into 3 modules, lasting 5 weeks each. In each module students were asked to analyze, discuss and reflect on different themes, connected to the course curriculum, and to build a conceptual map at the end of the activity. Groups were the same during the three module, and students in turn took specific roles: social "tutor", synthesizer, accountable for the conceptual map, "sceptical". Roles were assigned by the teacher at the beginning of each module. Measures and data analyses We analyzed students participation in the 3 different modules (subsequent in time) in terms of both posted and read notes in knowledge building forums. For the first question of inquiry, we compared participation in the three different periods of two groups of students: students who took a role in the second period ("with role in the second period") and students who didn't take a role at all ("without role"). So, in module 1, none of the students in the two conditions took a role in the group, in the second period students "with role" had particular responsibility in their group, and in the third period again none of the students had particular roles. We used Module 1 as a pre-test and Module 3 as post test and we analyzed differences using T-Student test. It was not possible to apply ANOVA for the lacking of the statistical conditions. Finally, for the third question of inquiry, we compared in a descriptive way, the writing and reading activity among the different roles.

Results

1st question of inquiry

The results evidence an higher participation (both in writing and reading notes) in each module among students who took a role in that period. Comparing students "without role" with students "with role in the second period", we can see that taking a role has an effect on writing activity also in module 3, when students do not have a specific role in the group. The two groups, in fact, do not differ in the Module 1 ($t(70) = 0,28, p > .05$) before the introduction of the design variable. Significant differences emerged in the Module 3 ($t(70) = -3,64, p = .001$): the students "with roles in the second period" wrote a higher number of notes in the web-forum. We have a similar situation with reference to the reading activity. Also in this case we have not differences in Module 1 ($t(70) = -1,11, p > .05$) between the two groups. In the Module 3 the students "with role in the second period" read a higher number of notes compared their counterparts ($t(69,5) = -3,41, p = .001$).

2nd question of inquiry

Concerning the second question of inquiry, the analysis of the participation considering the particular kind of role assumed by the students shows some differences. In each module the students more active in writing had the role of synthesizer of the group discussion, followed by the social tutor.

Discussion

These results show that students assuming a role in an on line course are more active in terms of writing and reading activity in the on line environment, and this activity remain high also when they end to take a role. Probably this is due to the cognitive responsibility they take in order to build knowledge in the group. Scardamalia (2002) express this in terms of a "collective cognitive" responsibility activated in the students participating in a Knowledge Building Community, also if the author does not mention the role assumption. It is also interesting to notice that the synthesizers of the group discussion are the students more active within the students assuming a role. This can confirm the previous idea, because, who works on the synthesis have the responsibility to define the advancements of knowledge of the community. Probably, then, he tends to stimulate the knowledge building process in the community through a more frequent writing activity .

PAPER PRESENTATION

Improving non-academic laypersons' knowledge and skills to evaluate source information on the Web

Yvonne Kammerer, Knowledge Media Research Center, Germany; Dorena Amann, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

This paper reports on the development and evaluation of the Web training TESWIN. TESWIN aims at improving non-academic adults' source evaluations during Web search for science-related issues, such as medical and healthcare information. The necessity of such a training is given by the increasing popularity of the Web as an information source for science-related contents on the one hand, and by previous research demonstrating Web users' lacking knowledge and skills to evaluate Web-based source information on the other hand. Contrary to already existing trainings, TESWIN is specially designed for non-academic laypersons, focusing on three components, that is, 'the importance of evaluating Web information, 'learning how to evaluate', and 'the comparison of information across different sources'. To test the effectiveness of the TESWIN training, we conducted a study with N=51 participants who were randomly assigned to a training group or a control group. The training group first received the TESWIN training and then conducted a Web research about a health-care topic, whereas the comparison group was required to complete the Web search task before receiving the TESWIN training. With regard to participants' Web search behavior, such as the type of Webpages accessed and the time spent on different types of Webpages, as well as their search outcomes, that is, the quality of decision making and of argumentative summaries, the training group significantly outperformed the control group. Thus, TESWIN seems to be a promising way to improve non-academic laypersons' knowledge and skills to evaluate source information during Web search for science-related contents.

In recent years, the World Wide Web (WWW) has evolved into a major information source for science-related contents. Particularly in the context of personal concerns of individuals, such as medicine and health care, using the Web as a supplement to the interaction with experts has become increasingly popular among laypersons. However, as anyone can publish virtually any information on the WWW, information sources on the Web differ dramatically with regard to authors' expertise and motives. Moreover, contrary to traditional information sources such as printed publications, documents on the Web seldom have explicit editorial review policies or undergo quality controls. Hence, Web users themselves are responsible for "gatekeeping", that is, evaluating the relevance and quality of information found on the Web. Previous research, though, has shown that searchers often lack prerequisite knowledge and skills to evaluate source information on the Web. Therefore, in recent years researchers have aimed at developing trainings for school or university students to foster Web search and evaluation skills (e.g., Gerjets & Hellenthal-Schorr; Walraven, Brand-Gruwel, & Boshuizen, 2010; Wiley et al., 2009). Up to now, another important target group for Web trainings has been neglected, namely non-academic adults. In contrast to today's students who have grown up using the Internet, non-academic adults have not learned to use the Web for science-related purposes in school or university. Thus, they can be assumed to face even bigger difficulties with evaluating Web information than today's students. Hence, we developed the Web training TESWIN (Training to Evaluate Science-related Web Information for Non-academics) that aims at teaching non-academic adults how to evaluate source information during Web search for science-related information (using the example of medical treatments). The TESWIN training, which is Web-based and self-paced, consists of three main parts:

First, the importance of source evaluations during Web search is illustrated.

Second, individuals learn how to evaluate sources, both when selecting search results presented by a search engine and when having accessed a Webpage.

Specifically, the focus is on the following four aspects of source information: document type (e.g., scientific article, private blog, commercial information), motives of the information provider (e.g., to inform, to exchange experiences, or to persuade), expertise of the information provider, and currency of the information.

Finally, the third part addresses the comparison of information across different sources to identify corroborated, unique, or discrepant information. All parts of the training contain a mix of declarative information, concrete examples, as well as several interactive exercises with feedback to apply the declarative information. Completing the training takes approximately 20 minutes. In order to test the effectiveness of the TESWIN training, we conducted a

study with 51 participants (mean age: 43.25 years; 45.1% male) without college or university education. Twenty-six participants were randomly assigned to the "training" group and 25 to a "control" group. In the training group participants received the TESWIN training and subsequently were required to conduct a Web search about "the effectiveness of L-Carnitine for sports performance" in order to give informed advice to a fictitious friend. In the control group, in contrast, participants received the TESWIN training only after having conducted the Web search task about the effectiveness of L-Carnitine. To complete the L-Carnitine search task, both groups were presented with 18 preselected search results presented on two subsequent Google-like search engine results pages (SERPs). Participants could access all Webpages associated with the search results. These were all relevant to the search topic with respect to the content of information provided, but reflected the large heterogeneity of information sources on the Web including six "objective" sources (e.g., official reports), six "subjective" sources (e.g., forum discussions), and six "commercial" sources (e.g., nutrition shops). Search time was limited to five minutes. Subsequent to the search task participants were given ten minutes to make a final decision about the effectiveness of L-Carnitine for sports performance and to write an argumentative summary on this issue.

Comparisons were made between the training group and the control group on participants' search process (i.e., the type of Webpages accessed during Web search and the time spent exploring the pages), as well as on their final decision and summary quality.

Results showed that the TESWIN training had a positive effect on participants' source evaluations as well as on their search outcomes. During Web search participants in the training group as compared to participants in the control group accessed significantly more "objective" Webpages ($p=.04$) and significantly less "subjective" ($p=.01$) and "commercial" Webpages ($p=.04$). Likewise, they spend more time on "objective" Webpages ($p=.001$) and significantly less time on "subjective" ($p=.02$). Furthermore, in line with scientific evidence reported in the Webpages, all but one participant in the training group made the decision that L-Carnitine was not effective to enhance sports performance, whereas in the control group only 15 participants made this decision (pTo conclude, our TESWIN training seems to be a promising way to improve non-academic laypersons' knowledge and skills to evaluate source information during Web search for science-related contents. Yet, further research is needed to investigate long-term results as well as transfer effects on science-related contents other than medicine and health care.

PAPER PRESENTATION

Collaborative literacy: Students exploring multiple online sources

Carita Kiili, University of Jyväskylä, Finland; Leena Laurinen, Agora, Psykocenter, University of Jyväskylä, Finland; Miika Marttunen, University of Jyväskylä, Finland

This study examines how students construct meaning and knowledge in a collaborative online reading situation. Student pairs ($n=19$) were asked to write a joint essay on a controversial issue. First, the pairs discussed the topic freely in order to activate their prior knowledge; next, they gathered source material on the Internet, and finally composed a joint essay. The data was collected using an interaction method (Miyake, 1986) and screen captures. At the beginning of the data analysis, the text-processing episodes ($n=195$) were separated from the interaction protocols. The text-processing episodes were divided according to the four-part model of collaborative reading patterns ($n=435$): individual vs. pair acquisition and clarification of information and individual construction vs. pair co-construction of meaning and knowledge. One individual reading pattern, silent reading, was added because it is impossible to say whether a silent reader is acquiring or constructing knowledge. A hierarchical cluster analysis was conducted to identify students' collaborative reading profiles. The students' joint essays were evaluated by teachers. Five different collaborative reading profiles emerged: co-constructors (2 pairs); collaborators (2); blenders (6); individually oriented readers (4); and silent readers (5). The reading profile seemed to reflect to the quality of the students' essays. The co-constructors' essays got the best marks whereas the silent readers got the weakest ones. Overall, it appeared that some students were capable of working as pairs whereas others had a stronger preference for working alone. Collaborative profiles might offer teachers an evaluative and instructional tool to support collaborative interaction in their classrooms.

The present study examines how students construct meaning and knowledge in a collaborative online reading situation. To be able to utilize multiple texts for the construction of knowledge, readers have to engage in a deep-level of text-processing: go beyond the literal comprehension of the text by connecting the text both with their prior knowledge (King, 2007) and with previously read texts. Reading that concentrates on gathering facts from the text as such may not produce more than raw material from which knowledge may be constructed (Volet, Summers, & Thurman, 2009). Unfortunately, recent studies of online reading (Jedekog & Nissen, 2004; Kiili Laurinen, & Marttunen, 2009) indicate that many students concentrate on locating and gathering information at the expense of deep processing of the information they find. This indicates that students need purposeful educational tasks that direct their thinking processes towards knowledge construction. Wells (2007, p. 264) argues that knowledge is most fully achieved in dialogue, when people are trying to solve problems, construct an explanation, or decide a course of action. In the present study we examine how students collaborate when they search for information on the Web to explore multiple perspectives on a controversial issue.

Methods

In the present study the students (n=38) were divided into pairs and they were asked to write a joint essay on the issue Should Internet censorship be tightened? First, the pairs were asked to discuss the topic freely (10–15 minutes) in order to activate their prior knowledge; next they gathered source material on the Internet (30 minutes), and finally composed a joint essay (45 minutes). The data consisted of 19 dyadic discussions (interaction protocols), when the students were searching and reading source material online. A computer program was used to capture all the activities the students conducted on the Web.

At the beginning of the data analysis, the text-processing episodes (n=195) were separated from the interaction protocols. After that, the text-processing episodes were divided into collaborative reading patterns (n = 435) on the basis of the four-part model with two dimensions: individual−collaborative and information acquisition − knowledge construction. The collaborative reading patterns were as follows: 1) individual acquisition and clarification of information; 2) individual construction of meaning and knowledge; 3) pair acquisition and clarification of information; and 4) pair co-construction of meaning and knowledge. One individual reading pattern, silent reading, was added because it is impossible to say whether a silent reader is acquiring information or constructing knowledge. A hierarchical cluster analysis was conducted to identify students' collaborative reading profiles. The analysis was based on five variables concerning the proportion of time each student pair spent on the five reading patterns. The students' joint essays were evaluated by four teachers who jointly determined the evaluation criteria to be applied. The essays were evaluated as outstanding (3), excellent (2), or good (1).

Findings

Five different collaborative reading profiles emerged: Co-constructors (n=2) engaged in collaborative text-processing with a strong emphasis on co-construction of meaning and knowledge (83.48% of text-processing time).

Collaborators (n=2) engaged mostly in collaborative text-processing. They used 46.36% of their text-processing time on pair acquisition and clarification of information and 40.84% on co-construction of meaning and knowledge.

Blenders (n=6) mixed collaborative (54.99 %) and individual (45.01%) modes of text-processing most equally. They spent most of their time on co-construction of meaning and knowledge (37.07%) and on silent reading (33.79%).

Individually oriented readers (n = 4), spent more time on individual text-processing, with the emphasis on silent reading (50.26%), than on collaborative text-processing. Silent readers (n = 5) spent most of their working time on reading silently (80.69% of text-processing).

The average mark awarded the pairs' joint essays was 1.84 (SD = 0.77). The reading profile seemed to reflect to the quality of the students' essays. The co-constructors' essays got the best marks (m=3.0) whereas the silent readers (m=1.2) got the weakest marks.

Conclusions

Overall, collaborative work during reading and writing seems to be beneficial for students. Firstly, teachers evaluated the joint essays better than the individual essays, which students normally write. Secondly, this study suggests that an argumentative task assignment conducted in a collaborative reading situation promotes information processing that goes beyond the facts presented in the texts. In the previous study (Kiili et al., 2009), in which students worked individually on the Internet in order to find information for an essay, the students concentrated mainly on gathering facts: 80% of all reading strategies were classified as fact gathering. The corresponding percentage in this study was only 38.

However, not all students are capable of taking full advantage of the collaborative situation. These students have a stronger preference for working alone. This would suggest that, in future, attention should be paid to developing methods for teaching students how to collaborate productively. Collaborative profiles might offer teachers one evaluative and instructional tool to support collaborative interaction in their classrooms.

PAPER PRESENTATION

Scaffolding information problem solving in web-based collaborative inquiry learning

Annelies Raes, Ghent University, Belgium; Tammy Schellens, Ghent University, Belgium; Bram De Wever, Ghent University, Belgium; Ellen Vanderhoven, Ghent University, Belgium

This study investigated the impact of different scaffolding conditions on students who are learning science through a web-based collaborative inquiry project. This project aimed to improve knowledge construction, as well as information problem solving (IPS) skills on the internet (strategy use), and metacognitive awareness (knowledge about cognition and regulation of cognition). Three experimental conditions (human tutor as an external regulating agent, embedded question prompts (EQP), and both forms of support) were compared with a control condition in a two-by-two factorial quasi-experimental design with 347 students involved. Findings revealed that students of all conditions make significant improvement in terms of the four dependent variables (knowledge construction, strategy use, knowledge about cognition and regulation of cognition). Yet, the learning gain significantly differs based on the scaffolds students are provided with. Providing students with EQP and a human tutor whose role is to facilitate the use of online search strategies and self-regulatory processes leads to statistically significant higher performances comparing to the other conditions. Only with regard to regulation of cognition and strategy use, EQP alone is as effective as the condition with EQP and human tutor. Providing students with only a human tutor, however, didn't seem to provide enough help by itself without incorporation of the embedded prompts. In this respect, our findings support the notion of multiple, distributed scaffolding as an approach to enhance web-based inquiry learning in complex classroom environments.

Theoretical background

Information and computer technologies are receiving increased attention in education because of their potential to support new forms of collaborative inquiry (Roschelle, Pea, Hoadley, Gordin, & Means, 2000) and the Web is more frequently used as a classroom and information resource (Large & Beheshti, 2000). Research indicates that computer technology can support learning, more specifically with regard to the development of higher-order skills such as scientific inquiry (Linn, Clark, & Slotta, 2003). However, this cannot be taken for granted. Particularly germane to web-based inquiry projects are the skills and processes associated with searching, evaluating, and understanding information sources which require regulation to learn about complex and challenging science topics (Brand-Gruwel, Wopereis, & Walraven, 2009). Yet, contemporary research has shown that most students have poor self-regulatory skills and use ineffective strategies (Azevedo, Moos, Greene, Winters, & Cronley, 2008). These findings stress the need to effectively scaffold the web-based inquiry process. Providing students with computer embedded scaffolds can be a method for improving students' regulation of web-based learning (Azevedo & Hadwin, 2005; Reiser, 2004). However, it is found that in the dynamic, complex environment with learners in a classroom, not all of the necessary scaffolding can be provided with only one tool or agent (Puntambekar & Kolodner, 2005; Tabak, 2004). Consequently, it is suggested to present multiple types of support for successful learning. Additional support can be provided by the teacher or human tutor (Azevedo et al., 2008; Wood, Bruner, & Ross, 1976). This study provides insight into these different modes of scaffolds and how they benefit students' learning through web-based inquiry. In our analysis of students' learning, we examined (1) knowledge construction, (2) IPS skills (strategy use), and (3) metacognitive awareness (knowledge about cognition and regulation of cognition).

Method

During a four-week field study students had to work on an inquiry based science project about climate change. Pretest-posttest differences in students' knowledge construction, strategy use and metacognitive awareness were measured. In total 347 students from 18 secondary school classes (grade 9 and 10) were involved and the classes were randomly distributed over the 4 conditions. Three experimental conditions were compared with a control condition in a two-by-two factorial quasi-experimental design (see table 1). The conditions differed in the provided type and amount of scaffolding during online inquiry.

Table 1: Quasi-experimental

The pre and post achievement test consisted of eight assessment items, 4 open-ended knowledge questions and 4 multiple-choice items, in which students were asked for explanation. To measure students' strategy use, they were faced with a scientific controversy problem. They were asked to take a stand that had to be justified with appropriate evidence from the web. Students were asked to describe in detail their strategy for searching for evidence and formulating their position. Finally metacognitive awareness was measured by means of an adapted version of the Metacognitive Awareness Inventory (Schraw & Dennison, 1994), which supports the two-component view of metacognition, i.e. knowledge about cognition and regulation of cognition.

Results

Our results indicate that learning science by means of a web-based inquiry project is effective to enhance learners' knowledge construction and to enhance their strategy use and metacognitive awareness. We can conclude this based on evidence for an overall increase in students' performances. However, pairwise comparisons show that the learning gain significantly differs based on the scaffolds students are provided with. Providing students with embedded question prompts and a human tutor whose role is to facilitate the use of online search strategies and self-regulatory processes leads to statistically significant higher performances comparing to the other conditions. Providing students with only embedded question prompts is as effective as the condition with EQP and human tutor with regard to regulation of cognition and strategy use. Providing students with just a human tutor, however, doesn't provide enough help without incorporation of the embedded prompts. In this respect, our findings support the notion of multiple, distributed scaffolding as an approach to enhance web-based inquiry learning in complex classroom environments.

PAPER PRESENTATION

Dialogical perspective for collaborative learning

The aim of this paper is to deepen the theoretical understanding of collaborative learning by focusing on the interrelationship of dialogue, context, temporality and learning, that is to say, dialogicality. Dialogical perspective for collaborative learning proposed here combines different theoretical approaches; both the theories of learning and theories of discourse. Bringing these perspectives together provides resources for the study of relationships among discourse, learning, and context that neither perspective can provide alone. Sociocultural theory is a theoretically framed approach to the study of learning and development as social constructions. In this study it is then used aligned with theories of language and discourse that build on the notion of (learning) contexts as being socially constructed. The notions of dialogicality, intertextuality, dynamic and historical nature of discourse and contextual resources all refer to the fact that any discourse or activity in which the individuals are involved takes its meaning with respect to other discourses and activities in which they have been involved or have some representation of. Hence, all collaborative moments are intertwined with other (past and future) situations that enable the subjects to make sense of the present situation. From the dialogical perspective collaborative learning can then be conceptualised as the collective process of innovative and interpretative reproduction of knowing and acting through different resources (or cultural tools) and their connection. In the presentation, along with the theoretical elaboration on collaborative learning, empirical examples are explored to highlight the dialogical nature of collaborative learning and methodological means for studying it.

In the area of collaborative learning, the focus of research has increasingly shifted from the outcomes and products of collaborative work towards the analysis of the processes of collaboration. This shift indicates an attempt to gain understanding about the nature of productive joint activity and to identify interactional features important for collaborative learning. In general, this "interactions paradigm" involves categorising students' interaction and correlating the frequencies of categories with learning outcomes (Baker, 2010). Baker (2010) calls this approach a "standard approach" and argues that the problem with this approach is that it does not take into account collaboration as a process of collective thinking manifested in and by dialogue. This kind of approach therefore discards the content and nature of knowledge construction that takes place in interaction between the collaborators. It has been argued that the "standard approach" reflects more broadly a view where language is isolated from its environment and a dichotomy is created between text and context (Goodwin, 2000), or between mind and world (Grossen, 2009). In the study of collaboration this has meant a separation of collaborative talk from the material and socio-cultural contexts in which it is embedded. Thus, in order to analyse collaborative learning we need to move from analysing structures of talk separated from their contexts toward a more dialogical approach for studying learning. This means both studying collaboration as a dialogue and the need to explore how material and sociocultural aspects mediate students' discursive activity.

The aim of this paper is to deepen the theoretical understanding of collaborative learning by focusing on the interrelationship of dialogue, context, temporality and learning, that is to say, dialogicality. Dialogical perspective for collaborative learning proposed here combines different theoretical approaches; both the theories of learning and theories of discourse. Bringing these perspectives together provides resources for the study of relationships among discourse, learning, and context that neither perspective can provide alone. Sociocultural theory is a theoretically framed approach to the study of learning and development as social constructions (Vygotsky, 1978; Wertsch, 1991). In this study it is then used aligned with theories of language and discourse that build on the notion of (learning) contexts and situations as being socially constructed (Gee & Green, 1998; Linell, 1998). These perspectives targets attention to the dynamic and interpretive nature of participants' actions and discourse, and how - through these actions and discourse - the participants shape and are shaped by the context being constructed. The context constructed involves aspects of the physical, social, cognitive and cultural environments that become relevant through the participants' activity and discourse. Participant's personal, social and cultural knowledge can be called mediated and abstract contextual resources (Linell, 1998) or aspects of situation (Gee & Green, 1998) that are reflected and constructed through participants' discursive activity. For example, the participants may draw on some past experience that is used as a resource for building understanding in the present situation, or the discourse may reflect norms, values, and expectations related to participants' communities. This highlights the historical nature of discourse pointing to the fact that discourse is mediated by the historical, institutional and socio-cultural contexts (Mercer, 2008). Immediate and concrete contextual resources or material aspects of situation, in turn, refer, for example, to physical spaces, persons, objects, artefacts and co-text that are referred to in discourse and mediate discourse. Co-text – e.g. preceding discussion - that is actively used in the "new act of sense-making" (Linell, 1998), is what makes discourse a dialogue. Co-textual referencing in discourse underlines its dynamic nature (Mercer, 2008). It shows how discourse emerges and speakers' contributions are contingent on what the other speakers say. The dynamic and historical nature of discourse is in line with Grossen's (2009) notion of spatial and temporal dialogicality meaning that in discourse there is always a here-and-now and there-and-then of the encounter. According to Gee and Green (1998),

one function of talk is "connection building", which refers to the intertextual ties that are constructed by participants in their joint meaning making. Intertextual ties are those connections that the participants in the group reflect, and make to different aforementioned aspects of a situation, or resources. The notions of dialogicality, intertextuality, dynamic and historical nature of discourse and contextual resources all refer to the fact that any discourse or activity in which the individuals are involved takes its meaning with respect to other discourses and activities in which they have been involved or have some representation of. Hence, all collaborative moments are intertwined with other (past and future) situations that enable the subjects to make sense of the present situation. From the dialogical perspective collaborative learning can then be conceptualised as the collective process of innovative and interpretative reproduction of knowing and acting through different resources (or cultural tools) and their connection. In the presentation, along with the theoretical elaboration on collaborative learning, empirical examples are explored to highlight the dialogical nature of collaborative learning and methodological means for studying it.

PAPER PRESENTATION

Digital Video as a Tool to Support Learning

Carmen Zahn, Knowledge Media Research Center, Germany; Karsten Krauskopf, Knowledge Media Research Center, Germany; Friedrich Hesse, Knowledge Media Research Center, Germany; Roy Pea, Stanford University, Wallenberg Hall (Room 232), United States

The potentials of digital video technologies reach far beyond the dynamical presentation and illustration of instructional information. They additionally encompass the collaborative exploration of video-based information in groups as well as the collaborative analysis of and reflection on video-based information in distributed communities of learners. Open research questions relate to the effectiveness of using these affordances for active learning in school-based education – thus expanding traditional teacher-centered approaches, whereby videos on curriculum topics are only watched by individual learners or in whole-class models. In our contribution we will present empirical evidence from an experiment on the use of digital video tools to support students' collaborative learning through design in history lessons. Precisely, we investigated 16-year old learners (N=148) jointly elaborating on a history topic with the help of web-based video tools during a design task. We compared two types of video tools (analysis tool vs. integration tool), as well as two contrasting types of instructive guidance for student collaboration in dyads (cognitive task related guidance or social interaction related guidance). Both types of guidance and tools aimed at supporting students' active and meaningful learning and critical reflection on the history topic. Results indicate that social interaction related guidance was more effective in terms of learning outcome (e.g., critical reflection skills) than cognitive task-related guidance. The different tools did not yield significant differences in learning. The practical implications of these results will be discussed.

Digital video technologies provide a variety of tools to support collaborative learning including functions for editing, or contextualizing digital videos. Learners may zoom into and out of digital video sequences, they may insert hyperlinks into digital video in order to relate visual information to other instructional materials and they may arrange digital video sequences for discussion and reflection. Such functions are expected to afford, for example, detailed observation (Smith and Reiser, 2005), or understanding of complex concepts in ill-structured domains (Spiro, Collins & Ramchandran, 2007).

The affordances of digital video technologies can be restructured for youthful learners in classrooms, so that students can either create their own representations (e.g., multimedia documents) or arrange video contents in order to understand and explain complex subject matter. This usage in a sense of learning through design (e.g., Kafai & Resnick, 1996) goes far beyond teacher-centered approaches, whereby videos on curriculum topics are only watched by individual learners or in whole-class models.

The aim of our contribution is to present empirical evidence on the use of collaborative video tools used to explore historical film sources during a design task in a history lesson in order to learn about a topic and thereby critically reflect on the sources as products of a specific period in history. Over the last years, evidence from experimental studies has indicated that specific affordances of video tools (e.g., of WebDiverTM, Pea, et al. 2004) employed in design tasks for history learning can guide and improve learners' social interactions and grounding processes to become more productive than those performed with simple technological solutions (Zahn, Pea, Hesse & Rosen, 2010). Yet, initial field studies (Zahn, et al., 2010) with 16-year-olds showed that the positive effects of video tools were sometimes limited and students would have needed specific instructive guidance to optimize their collaboration. This finding is consistent with findings from Barron (2003) showing that student groups can have problems to engage in productive knowledge-building conversations during video-based mathematics problem solving. Also, collaborating students need help in organizing, planning and conducting inquiries (Edelson, Gordin & Pea, 1999), choosing appropriate learning strategies (O'Donnell and Dansereau, 1995), and argumentation (Kollar & Fischer, 2004).

Here, we thus examine the open question of instructive guidance for students' collaborative learning through design using digital video technology in history lessons. 148 students from four different German high schools located in Southwestern Germany participated in the study. Their mean age was $M = 16.2$ years ($SD = 1.0$). The study was conducted in a computer classroom set up at the Knowledge Media Research Center, Tuebingen, Germany (KMRC). Students were randomly grouped into dyads and assigned to one of four conditions conforming to a 2×2 study plan. The first factor (Guidance) determined which type of instructive guidance was provided as support for the collaborative accomplishment of a specific visual design task. The second factor (Video Tool) determined which video technology the students used. Guidance varied by focusing either cognitive design related vs. social interaction related issues. The Video Tool factor varied in terms of whether the students worked with „WebDiverTM“ for analysis and guided noticing or „Asterpix“ for integration and hyperlinking of video information.

Results indicate that using either of the video tools (WebDiver or Asterpix) was generally effective and effectiveness did not differ between conditions. However, variations in instructive guidance (cognitive task related vs. social interaction related guidance) resulted in different learning outcomes: ANOVAs revealed that with social interaction related guidance, the students' immediate products of task work – the design products – were of better quality, and scores in a transfer test measuring individual skills of critical analysis of a video message were significantly higher ($F(1, 68) = 7.96, p = .01, \eta^2 = .11$). No differences emerged concerning performance in a multiple-choice posttest on factual knowledge about the topic indicating that there was no „trade-off“ with knowledge acquisition. No differences were found in the amounts of time devoted during the students' dyadic interactions to „planning“, „evaluation“, „technical issues“, „problems“ or „off task“ behaviors indicating that the better learning outcomes were not due to differences in time on task. This leads us to the conjecture that the dyads with social interaction related guidance learned more effectively than the dyads cognitive task related guidance due to qualitative differences in dyadic interactions. In a next round of analyses we will specify these quality differences. So far, we conclude that guidance addressing the cognitive task of design did not further improve learning (nor did it improve the design products), but guidance improving social interaction did. For teachers using video technology in their classrooms this aspect would be practically important if indeed their feedback during collaborative design would not focus on the emerging design product, but on social interaction and knowledge advancement – as was suggested earlier for hypertext projects by Bereiter (2002).

PAPER PRESENTATION

Investigating the interaction effect between positive interdependence and individual accountability

Kwaku Frederick Sarfo, University of Education, Winneba, Ghana

This paper is aimed at investigating the interaction effect between positive resource interdependence and individual accountability on performance of individuals in cooperative working group. To achieve the purpose of the study 2 by 2 post-test experimental design was conducted to test the formulated hypotheses. Descriptive statistic and univariate analysis were used to analyse the data. The result shows that there is no interaction effect between positive resource interdependence and individual accountability. Interestingly, the results of the study reveal that when each member in the cooperative working group works on the full content of the information before group discussion they academically perform better than when each member in the group works on the part of the content before group discussion. Furthermore, the result of the study indicates that when members in cooperative working group are informed that there will be a random examination and the student's score will be the score for the rest of the group members and the score will be part of the final grade, it strengthens individual and group accountability and therefore facilitates learning. The theoretical and practical implications of the results were discussed.

Ability to work successfully in a group, critical thinking, problem solving and reflective thinking are very important in the modern aims of education and the world of work. Cooperative learning is acknowledged in the literature on learning and instruction (e.g. Slavin, 1991, Johnson & Johnson, 1998; Johnson, Johnson, & Holubec, 1998, 1999) as one of the teaching strategies that facilitates the learning processes for development of knowledge and skills that are required in the modern education and the world of work.

Cooperative learning group is based on the principle of social cognition by Vygotsky (1978) that social interaction has a dramatic impact on cognitive development. Biological and social development are not isolated from each other, and learning is largely mediated by social interaction of students and "more knowledgeable others" (teachers, parents, coaches, peers, experts, etc) (Driscoll, 1994). More recently, cooperative learning strategy has enjoyed a lot of attention in the literature on social constructivist and cognitive learning principles, and it is particularly prevalent in education and training institutions and e-learning environments. In spite of the fact that cooperative learning strategy has received remarkable attention in instructional community, empirical studies conducted on its effectiveness reveal mixed findings. On the one hand, research findings (e.g., Slavin, 1991; Chang & Mao, 1999; Fuchs, Fuchs, Mathes, & Simmons, 1997; Onwucabuzie, Collins, and Thao 2009; Merina, 2009) show that cooperative learning group enhances acquisition of social skills and academic performance. On the other hand, studies conducted on effectiveness of cooperative learning group (e.g Boyle 2010; Krause, Stark, Mandle 2009; Candas, 2009) indicate that cooperative learning group does not enhance academic performance. Based on these mixed findings and taking into account the recognition of cooperative learning strategy in instructional practice, there is the need to conduct further empirical studies to investigate and contribute to the theoretical understanding and practical implications of cooperative learning group. In cooperative learning group positive interdependence, more specifically positive resource interdependence and individual accountability are used to strengthen the achievement of the learning goal by the individuals and the entire group (Johnson, Johnson, & Holubec, 1998).

This paper is aimed at investigating the interaction effect between positive resource interdependence and individual accountability on performance of individuals in cooperative working group. To achieve the purpose of the study, 2 by 2 post-test experimental design was conducted. One hundred first year university students were randomly exposed to positive resource interdependence condition consisting of two different treatments: 1) full content and 2) part content; and individual accountability condition consisting of two different treatments: 1) told and 2) untold. The average age of the students was 25 years. The content for the treatments was the events of instruction by Gagne (1985) selected from *Psychology of learning for instruction* (Driscoll, 2005). The test items were six retention and transfer questions on the events of instruction. The experiment was conducted in the regular classroom to test the following hypotheses: 1) There is an interaction effect between positive resource interdependence and individual accountability on the performance of cooperative working group; 2) In cooperative working group if all the learners are asked to master the whole content before they work cooperatively to achieve the group's goal, it leads to more

effective learning than asking each of the learners to master part of the content; and 3) when members in cooperative learning group are informed that there will be a random examination and the student's score will be the score for the rest of the group members and the score will be part of the final grade, it strengthens individual and group accountability and therefore facilitates learning. Descriptive statistic and univariate analysis were used to analyse the data.

According to the results there was no interaction effect between positive resource interdependence and individual accountability on cooperative working group. Interestingly, the results of the study revealed that when each member in the cooperative working group works on the full content of the information before group discussion they academically performed better than when each member in the group works on the part of the content before group discussion. Furthermore, the result of the study revealed that when members in cooperative learning group are informed that there will be a random examination and the student's score will be the score for the rest of the group members and the score will be part of the final grade, it strengthened individual and group accountability and therefore facilitates learning. The theoretical and practical implications of the results on cooperative learning (for instructional designers and educational practitioners) were discussed.

PAPER PRESENTATION

Day Schools: Their Use and Pedagogical Quality from a multidimensional view

Esther Forrer Kasteel, Hochschule für Soziale Arbeit, Switzerland; Patricia Schuler, Pädagogische Hochschule, Switzerland

In the German speaking countries the topic of day schools is being discussed with a growing focus on the area of institutional quality. There have been few empirical studies conducted in this area, except with regard to the StEG-Study (Fischer/Kuhn/Klieme 2009) in Germany and the Edu-Care-Study (Schýpbach 2010) in Switzerland. The study "Evaluation of Day Schools in the City of Zurich" draws upon these research projects. It focuses on the pedagogical qualities of two day school models, those which offer a compulsory whole day attendance for children (day schools) and those which allow for a more flexible combination of attendance (so called school clubs). Both a quantitative and qualitative research analysis was conducted. The sample group included all forms of day schools in the city of Zurich. The results show that the parents of children in both day school models are very content with the services offered by the schools and that the students frequently use these. The qualitative interviews with the principals, teachers and child care taking personnel furthermore show that to build up a successful school culture and identity, a high level of cooperation in the school team is of greatest importance.

The demand for day schools or all day educational programmes for children and adolescents in Switzerland and Western Europe is steadily increasing. Yet in contrast to Scandinavian countries, which are clearly leading figures in this domain, Switzerland lags behind, offering few schools with all day care. The OECD (2001) points out that all day educational programmes and schools in Switzerland are developing more hesitantly than in other OECD countries.

Not only in the German speaking region of Switzerland but in the all German speaking countries are day schools an important aspect of the political agenda concerning education and it is also a key feature of current trends in education. Due to the fact that the demand for day schools is high the discussions circulate around the quantity thereof, not their quality.

The PISA study identifies that day schools and all day educational programmes hold within them an enormous potential, for they allow children to be surrounded by a stimulating social and educational environment and enable parents to pursue a career (Lanfranchi 2004). Research studies show that all day care taking structures for children are important areas of socialisation and education (NICH 1994; Lanfranchi 2002; Lanfranchi/Schrottman 2004). These empirical findings were strengthened by two large scale studies regarding all day educational programmes and day schools in Germany and Switzerland – StEG-Study (Study focused on the development of day schools in Germany: Fischer/Kuhn/Klieme 2009) and EduCare-Study (Schýpbach 2010).

With regard to the current discussion on school quality and school development it is the goal of the study "Evaluation of Day Schools in the City of Zurich" to focus on the pedagogical quality of day school programmes, thereby drawing upon the two largest studies in the German speaking region concerning this area. The study focuses on the pedagogical qualities of two specifically chosen day school models, namely schools which offer a compulsory whole day attendance for the children (day schools) and those which allow for a more flexible combination of attendance (so called school clubs). The aim is to collect empirical data which will enable the future development of both day schools models as well as all day educational programmes in the city of Zurich. The main focus of the study lies on the use of

different supervised services offered by the school, the quality of pedagogical services and frameworks, different forms of cooperation, as well as the general comparison of the two day school models.

In this cross sectional study the views of the parents as well as the principals, teachers and child care taking personnel were evaluated using quantitative and qualitative methods. The sample includes all day schools in the city of Zurich (five day schools and four school clubs). With regard to the quantitative part of the study the parents of children from day schools and school clubs from the City of Zurich were contacted, in total this included 1537 parents. Approximately half of the parents, namely 771 parents actually filled out the questionnaire. Wherever possible the questionnaire included scales from the StEG-Study (Quellenberg 2009) as well as the EduCare-Study (Schýpbach et al. 2008). With regard to the qualitative research, interviews were organised. In total nine interviews with the principals of the schools and four group interviews including teachers as well as child care taking personnel were conducted.

The results of the quantitative research show that there are three key factors which influence parents to send their child to a day school or school club. Primarily they value the high level of reliability that the schools provide, secondly the possibility of being able to combine having a family and career. Finally the parents also see the strong interaction between the school and the child care taking personnel as a key reason to send their child to a day school or school club. It becomes apparent that the parents of children in day schools have a higher appreciation for these areas than the parents of children attending school clubs. The parents of children attending school clubs tend rather to value the additional supervised activities that the school provides as well as the child's interest to attend such an educational institution. The parents of children from both school models rank the overall quality of the school very positively. This can also be seen with regard to the results of the indicators assessing overall satisfaction with the school. A total of 90% of the parents are content or even very satisfied with the school in addition to this every second person is fully satisfied with eight of the twelve indicators assessing satisfaction. The parents are though clearly less happy with the playground, the meals, the choice of supervised activities for the children and the costs for day care. The parents of children who attend day schools evaluate the indicators of satisfaction more positively than the parents of school club children. The parents of day school children also view the quality defining criteria with regard to the school structures, the pedagogical organisation of supervised and child care taking services as generally more positive. The pedagogical staff is evaluated most positively by the parents.

The qualitative interviews with the principals, the teachers as well as the child care taking personnel show that high levels of cooperation within the school teams is the key to the development of a successful school culture and identity. On the basis of mutual respect for one another, common goals as well as clear conflict management both school models are able to develop a fruitful educational environment. The result thereof is a changing view of the educational profession for all individuals taking part therein.

It appears that day schools achieve a higher level of cooperation in comparison to school clubs which results out of different domain specific structures such as proximity of all school related areas, the constant presence of the students, as well as the parental choice to send their child this to educational institution. In addition to this all schools uphold a distinct school culture and identity. Lastly the two school models coincide with the needs of the parents, for the school's top priority is to support the children on every level which is achieved by the cooperation of all members of the school team.

PAPER PRESENTATION

Pupils with behaviour problems in inclusive settings: Challenges for classmates and teachers

Annette Textor, Universitaet Bielefeld, Germany; Anna Funger, Universitaet Bielefeld, Germany

Inclusive Education with pupils who have emotional or behavioural difficulties is seen as particularly challenging (Dumke/ Eberl 2002, Sander 1998). Empirical findings about learning results and well-being of classmates are contradictory (Feyerer 1998, Dumke/Schaefer 1993, Wocken 1993, Zentall 1989) and incomplete, because studies about inclusive education do rarely regard the effects of different special needs, and the studies about children with emotional or behavioural problems mostly do not focus on systemic variables. On the other hand it must be expected that inclusion is going to increase in the next years due to political developments. On this basis, the research project "SISSI" examines inclusive education with students with emotional and social problems in primary schools and focuses on benefits and challenges for primary school teachers and for classmates in 19 inclusive classes with two hours of special needs education per week and 17 classes without inclusion. Findings suggest that reading performance and sociometric data in classes with inclusion of a pupil with behavioural problems are not different from those in the control group, but teachers find their work a little bit harder despite the additional resources they get. Since the special school still provides the possibility for primary schools to give very challenging pupils away, those findings have to be interpreted very carefully.

Inclusive Education with students who have emotional or behavioural problems is seen as particularly challenging. Teachers often think the behaviour of those students is difficult to handle for them and for the other students in the classroom (Dumke/ Eberl 2002, Sander 1998). On the other hand, an increasing tendency for mainstreaming children with special educational needs, especially with special needs concerning emotional or behavioural problems, is observed in Germany (KMK 2010). In the future it can be expected that this trend is accelerating significantly, due to political developments like the 2006 UN Convention on the Rights of Persons with Disabilities.

In contrast to the high relevance of including pupils with emotional or behavioural problems in mainstream settings, empirical findings are contradictory: Studies about inclusive education in common show that learning results and social cohesion of inclusive school classes are not less than those of regular classes without pupils with special needs (Huber 2008; Feyrer 1998; Dumke / Schaefer 1993). Furthermore, on the basis of the research about teachers' workload and social support it could be supposed that teachers benefit from the additional resources in inclusive settings (Schaarschmidt 2004, Rothland 2007). On the other hand, studies about children with emotional or behavioural problems suggest that classmates show high social distance to aggressive pupils (Wocken 1993, Preuss-Lausitz 1997), and children with hyperactive behaviour can influence their teacher and their classmates significantly (Zentall 1989, Campbell 1977). In total, studies about inclusive education rarely regard the effects of different special needs, although different dimensions of heterogeneity could cause different difficulties, and the studies about children with emotional or behavioural problems mostly do not focus on systemic variables like special resources that are provided for those children.

On this basis, the research project "SISSI" examines inclusive education with students with emotional and social problems in primary schools and focuses on benefits and challenges for primary school teachers and for classmates. The sample consists of 707 students in 36 classes and their class teachers. 19 classes include a student with special needs because of social or emotional problems, 17 classes are the control group. The classes in the study group are supported by a teacher for special needs education for two hours a week. Both kinds of classes – study group and control group – are similar concerning the social background of the pupils. In a longitudinal design with four times of questioning during one year, all students and teachers filled out questionnaires; the pupils of second classes were supported by a researcher. In addition, the reading skills of the students were tested four times. For data analysis quantitative (T-Tests and regression analyses; hierarchical multi-level analyses are planned) and qualitative methods are combined.

First Findings suggest that reading performance and sociometric data in classes with inclusion of a pupil with behavioural problems are not different from those in the control group. Pupils mention a similar number of classmates with whom they would like to play or to work in both settings, and they also mention a similar number of classmates they would work with by no means. Pupils like to play or to work with classmates they like (42%), with whom they are friends (30%), whom they adore for some reason (21%) or with whom they share interests (19%, the pupils could write as many reasons as they like). They do not like working with classmates who are aggressive (31%), whom they do not like globally (29%) or who break the rules in class or disturb their learning processes (21%). 17% of the pupils do not tell a reason why they do not like to work with some classmates, because there are no classmates they do not like to work with.

In the group of the teachers there are neither significant differences, but since the group is small, there are some non-significant effects worth being reported. The teachers in the study group like their job in a similar degree than the teachers in the control group. Furthermore, both groups feel a similar degree of quantitative overload, but teachers in the study group found their work a little bit more challenging and feel a little bit more isolated than teachers in the control group. They are more committed, but feel less under pressure to succeed. The teachers in the study group say they benefit from the cooperation with the special education teacher. Nevertheless, many of them would not like to have a pupil with behavioural and emotional problems in their next class again. In a group discussion, teachers were confronted with this contradiction. They explained that although they benefit from the cooperation, including a pupil with behavioural problems is challenging for them and before starting to work with this pupil, they do not know if they can handle it. So they conclude, if they had the possibility to choose, they would rather work in a regular class.

As a final result for pupils it makes no difference whether they are in class together with a pupil with social or emotional problems or not, but for the teachers, work gets a little bit harder. Nevertheless, these findings have to be interpreted very carefully: First, the teachers have the possibility to send pupils to the special school if they think that they cannot handle them in class – and in two of the 19 classes, this happens during the year of research. Second, the research area is a rural area and teachers say many classmates have good social skills and support the inclusion. So in total, better resources, first of all more hours of special teachers or more other professionals in each class, are desirable. Furthermore, the concepts of the visited schools are not really inclusive, because they only include pupils

with behavioural problems – slow learners for example still have to go to a special school. A fully inclusive concept would probably require more individualised learning and enhance the cooperation between teachers and other professionals.

PAPER PRESENTATION

The Role of Peer Facilitation in 3D Learning Environment

Paivi Poyry-Lassila, Aalto University, Finland; Timo Haukola, Aalto University, Finland; Riitta Smeds, Aalto University, Finland; Kristiina Kumpulainen, National Board of Education, Finland

Today's university graduates must be provided with the skills and competences for working with remote colleagues and solving complex problems collaboratively in virtual workspaces. The kinds of interaction and collaboration skills needed in virtual spaces urge us to re-consider the methods and pedagogy needed to support learners' active and productive participation in knowledge creation. In this paper we discuss a case study on a university-level course that was set to examine the role of peer facilitation in supporting students' interaction and learning in the context of 3D virtual spaces. Based on our empirical mixed-methods case study, we reflect on the effect of peer facilitation on interaction at virtual 3D learning environment. We compare facilitated and non-facilitated teams' interaction through survey data, chat log data and ethnography-informed analyses on video-recorded meetings in the 3D environment. The quantitative analyses on chat log and survey data indicate that there are differences between the facilitated and non-facilitated groups with regard to both amount and quality of communication. Furthermore, the ethnography-informed video analyses suggest that the facilitated teams became more fluent and efficient in collaboration, at least partly, as a result of peer facilitators' interventions. This research produces new knowledge and understanding on how to design instruction in 3D virtual settings. Especially it highlights the role of a peer facilitator in team interaction.

As today's work and business life require global collaboration, the university education has faced new challenges. The graduates must be provided with the skills and competences for working with remote colleagues and solving more and more complex problems collaboratively in virtual workspaces. The kinds of interaction and collaboration skills needed in virtual spaces urge us to re-consider the methods and pedagogy needed to support learners' active and productive participation in knowledge creation. In this paper we discuss a case study on a university-level course that was set to examine the role of peer facilitation in supporting students' interaction and learning in the context of 3D virtual spaces. Based on our empirical case study and data analysis, we aim to answer the following research question: What kind of effect does peer facilitation have on interaction at virtual 3D learning environment?

The context of this study was a global virtual collaboration project (GVCP) course that was designed and organized in 2010 co-operatively by five universities from Europe, USA and India. The objective of the course was to offer the students a possibility to discover and explore genuine challenges emerging from global team work and cultural differences, and develop skills and competencies needed in virtual collaboration.

The students (N=91) were located on three different continents, and during the course they solved in collaboration a real-life construction engineering problem by using a virtual 3D-environment "Second Life" as the primary arena for interaction. Seven structurally similar global teams were formed, and three of them had two additional students in the role of a process facilitator. By having both facilitated and non-facilitated teams, we were able to explore the role of peer facilitation in learning.

The pedagogical approach of the GVCP course is based on the socio-constructivist view on learning according to which learning takes place in and through social interaction (Lave & Wenger 1991). The pedagogical design of the course was built on the principles of problem-based learning (Capon & Kuhn 2004) and collaborative learning (Dillenbourg 1999). In addition, scaffolding (Pea 2004) and facilitation (Saranpää 2010) were central elements. The GVCP course aimed to develop the students' capabilities in self-directed learning through a facilitated and self-directed group work assignment (Grow 1991).

To develop students' skills in teamwork, knowledge acquisition, cooperation and respecting colleagues' views, the course followed a problem-based design (Wood 2003), and the students worked on a real-life case. The teachers acted as enablers and evaluators providing the framework and guidelines for the students' learning process. They intervened only when necessary, whereas the facilitator students assigned to half of the teams had an active tutor-like role (Neville 1999) supporting the problem-solving process through facilitation.

We define facilitation as helping people to navigate the processes that lead to agreed-upon objectives in a way that encourages participation and productivity (O'Hara-Devereaux & Johanson 1994). A facilitator supports the social group processes and maintains a propitious atmosphere for collaboration. Facilitators also contribute to the problem-

solving work by preventing counter-productive conflicts and by designing interventions that help others to progress. Facilitation has been shown to affect the quality of students' knowledge development (Ponte et.al. 2004).

In this research we applied the case study method with mixed methods approach (Creswell 2009). Empirical data was collected through three on-line surveys, automatically generated chat log data, and by video-recording the virtual team meetings (161). The surveys dealt with students' perceptions on conflicts and quality of communication in the 3D environment. We also collected the final grades of each student team.

The data was analysed in three phases. First, we analysed the quantitative survey data with basic statistical techniques, and calculated descriptive statistics from the chat log data. The quantitative analyses served as a background enabling us to form an initial understanding of the phenomenon and to design the qualitative video analysis. Second, an ethnography-informed analysis on the video recorded student team meetings in Second Life (60 hours) was implemented utilizing the ELAN software. Analysis was made on group level, a global student team being the unit of analysis. The facilitated teams' meetings were explored to find out what actually happened there, how the interaction unfolded, and how facilitation affected it. The non-facilitated teams' videos were used for comparison. Lastly, we compared the student teams' final grades.

The descriptive statistics of the chat log data showed differences between the teams. On average, the facilitated teams typed in total 5135 chat message, compared to the non-facilitated teams' 2063 messages. Furthermore, the survey data analysis indicated that peer facilitation affected the student teams' interaction; e.g. the facilitated teams had fewer conflicts, the conflicts were discussed more, and the members were less pushing their personal opinions during disagreements. Additionally, facilitation affected positively the students' perceptions on the quality of interaction.

The ethnography-informed video analysis suggests that the facilitators were able to create a supportive atmosphere that had a positive impact on collaboration and interaction. The facilitators spontaneously created a variety of extra interventions in addition to the predefined ones to enhance the group processes. Consequently, facilitated teams were able to agree upon responsibilities and work practices more quickly, and they also coped with unexpected situations more fluently and were in general more organized when compared to the non-facilitated teams. Yet, the final grades based on the written team reports did not differ between the facilitated and non-facilitated teams.

However, our other findings indicate that the course's overall aim was achieved better in the facilitated teams, as they seemed to have learned better virtual collaboration and communication skills through peer facilitation. Accordingly, the facilitated teams reached a deeper level of collaboration in studying.

This research produces new knowledge and understanding on how to design instruction in 3D virtual settings. Especially it highlights the role of a peer facilitator in team interaction. Findings presented have also potential significance to the management of virtual teams and their collaboration processes in work life.

PAPER PRESENTATION

Teachers/ joint discovery of solutions – training peer consulting skills

Monika Trittel, Technical University of Darmstadt, Germany; Bernhard Schmitz, Technical University of Darmstadt, Germany

Most of the time, teachers have to work on their own, whether it is preparing and giving lessons or consulting with parents (Vogt & Rogalla, 2009). Solutions for problems could be found more easily together with colleagues (Hasbrouck & Christen, 1997). However, the collaboration of teachers seems to be an exceptional case. The aim of our study was to develop and evaluate a training programme for teachers concerning peer consulting (Toman, 1996). Up to now, 29 teachers have participated in this ongoing study, which is based on an experimental 2 x 3 design, with the factors time and training programme. Within the experimental group "peer consulting", a within-subject-design with three repeated measurements was exerted. The training programme consisted of a theoretical input and practical peer consulting sessions. The preliminary results show a significant growth in knowledge about peer consulting for the experimental group, but not for the control group. The same could be found for the attitude concerning peer consulting. Across the three peer consulting sessions, a significant positive effect could be found regarding the willingness to reflect and the satisfaction with the method of peer consulting.

The results have to be regarded as preliminary results. Nevertheless, some interesting statements can be made. The method of peer consulting seems to be highly valued from educational practitioners. The training programme is expected to lead to more profound knowledge about peer consulting. An increasingly positive attitude towards it may ensure the transfer to real school life, beyond the borders of the training programme.

Teachers have to tackle manifold problems in everyday school life, for example individual students' difficulties with the learning matter or conflicts within a learning group. Most of the time, they have to work on their own, whether it is preparing and giving lessons or consulting with parents (Vogt & Rogalla, 2009). Many problems are common; they also exist for other teachers. Solutions could be found more easily together with colleagues (see Hasbrouck & Christen, 1997), who have the same background but a fresh view on things, or have perhaps already experiences with this problem. However, the collaboration of teachers seems to be an exceptional case, due to lacking structures and competences at school and, at least perceived, a lack of time. There is a necessity to support teachers to tackle educational problems (Weinert, Helmke, & Schrader, 1990). The aim of our study was to develop and evaluate a training programme for teachers, wherein the participants learn the basic principles and practice peer consulting or intervention (Toman, 1996), in order to be able to implement peer consulting groups on their own responsibility at their schools.

Up to now, 29 teachers have participated in this ongoing study, which is based on an experimental 2 x 3 design, with the factors time and training programme (no participation, participation in peer consulting, participation in diagnosing learning behaviour). The training programme "diagnosing learning behaviour" is conducted at present, so no results can be reported at this stage. Within the experimental group "peer consulting", a within-subject-design with three repeated measurements was exerted to evaluate the three practical exercises / peer consulting sessions. The training programme consisted of four modules. The first module was a theoretical input concerning i.a. structured communication, and the usefulness and application of peer consulting. The other three modules consisted of peer consulting sessions as exercises of transferring the theoretical input to practical execution.

The effects of the training programme for peer consulting were measured using a multilevel questionnaire, which was filled out before the first module and after the last module. It consisted of questions regarding the knowledge, self-assessment of competences and attitude concerning peer consulting, using multiple methods such as Likert scales and Semantic Differentials. Measuring in more detail the effects of the practical modules, the experimental group filled out a questionnaire after each of the three peer consulting sessions.

The results of the presently existing sample show a significant growth in knowledge about peer consulting for the experimental group, but not for the control group. The same could be found for the attitude concerning peer consulting. The experimental group responded more positively in the post-test compared to the pre-test, which was not true for the control group. Across the three practical peer consulting sessions, a significant positive effect could be found regarding the willingness to reflect ($M_1 = 23.89$, $SD_1 = 2.430$, $M_3 = 25.57$, $SD_3 = 2.992$ [$F = 7.341$, $p = .028$, $\eta^2 = .55$]) and the satisfaction with the method of peer consulting ($M_1 = 18.57$, $SD_1 = 3.505$; $M_3 = 25.00$, $SD_3 = 3.697$ [$F = 4.000$, $p = .047$, $\eta^2 = .599$]).

The results have to be regarded as preliminary results, because of the small sample size at present, ongoing deeper statistical analyses and the awaited results of the training programme "diagnosing learning behaviour". Nevertheless, some interesting statements can be made. The method of peer consulting seems to be highly valued from educational practitioners. The training programme is expected to lead to more profound knowledge about peer consulting. An

increasingly positive attitude towards it may ensure the transfer to real school life, beyond the borders of the training programme.

PAPER PRESENTATION

Interlanguage as bridging the gap between colloquial and scientific knowledge

Clas Olander, University of Gothenburg, Sweden

This study explores the idea that learning science involves learning to talk science focusing the intersection between conceptual aspects of learning biological evolution and social languages, especially colloquial, inter- and school science language. Data was generated in secondary school classrooms in two ways: firstly through a pre and post test design with written answers; including both open ended and multiple choice questions. Secondly, through video taped peer group discussions, which was as an integrated part of the actual teaching. Analysis of the pre and post test design shows that when comparing written answers the students answered significantly more in line with a scientific view a year after teaching. During the peer group discussions the students negotiated the meaning of the notions: need, randomness and development and they used all three social languages (colloquial, inter- and school scientific language). The findings reported in this study make it possible to argue that colloquial expressions are not a hindrance in students learning; on the contrary they are a resource. Furthermore, the verbalisation in an interlanguage makes it easier to communicate in social life, outside the science classroom, and thus it increases the possibility of further learning.

Aim

This study explores the idea that learning science involves learning to talk science (cf. Lemke, 1990) focusing the intersection between conceptual aspects of learning biological evolution and social languages (Bakhtin, 1981), especially colloquial, inter- and school science language. The research questions explore the ways students appropriate school science language and the first question, out of three, deals with a macro analysis of students learning outcome and the two following questions deals with a micro analysis of students talk during peer group discussions.

- 1) In what way does the students' written answer develop from before to after teaching?
- 2a) In what way are conceptual constituents of biological evolution construed in the students' discussion?
- 2b) In what way does colloquial, inter- and school science language manifest and interconnect in the students' Discussion?

Methodology

The study was carried out in a Swedish upper secondary school, in two classes with 48 students (17 years old). The teaching sequence about biological evolution consisted of eight lessons and was taught by the same teacher. Data was generated in two ways: firstly (related to question one) through a pre and post test design with written answers; including both open ended and multiple choice questions. Secondly data was generated, through video taped peer group discussions which were one of the lessons, out of eight lessons in the teaching sequence. The peer group discussion dealt with a multiple choice question formulated as:

'Throughout the course of evolution living organisms have developed a lot of different traits. What is the origin of this enormous variation?

- The traits arose when they were needed
- Random changes in the gene pool of the organisms
- Living organisms pursue development
- Great variation is needed in order to get balance in nature'

The assumption was the discussion of the question would open a dialogic space (Wegerif, 2008) where different views on the topic would be articulated and thus generate data in relation to research question 2a and 2b. In all, 29 students in 7 groups were included since they gave permission to be video taped. When performing the discussion they went to

an adjacent room, started a video camera, discussed, turned off the camera and continued to the next activity. The remaining 19 students in 5 groups had their discussion in another room and were not video taped.

The analysis principally included three steps:

- Quantitative and qualitative analysis of students' written answers with a pre- and post test design (connected to question 1)
- Quantitative and qualitative analysis of what notions were important in the students' peer group discussion (connected to question 2a)
- Qualitative analysis of shifts between different social languages in the students talk (connected to question 2b)

Findings

In relation to research question one and the first step of analysis there where a significant change (calculated with χ^2 -test) in the way the 48 students answered test items about biological evolution. When comparing written answers (before teaching started and one year after teaching ended) the students answered significantly more in line with a scientific view a year after teaching.

Concerning research question 2a and second analysis transcripts from the groups' discussion were first analyzed as a whole, meaning that all communication from seven groups (ranging between 6 and 19 minutes with an average of 11 minutes) were divided in sequences where different conceptual notions were discussed, no matter if they originated in colloquial or scientific language. Mainly three notions were negotiated by the students: half of the talking time need and randomness (mostly at the same time and in contrast to each other) were in focus and during a quarter of the time the notion of development was discussed. The remaining quarter dealt with a range of issues (HIV, twins, animal/humans etc).

Finally, when it comes to research question 2b and the last step of the analysis the results are exemplified below with an excerpt from one peer group discussion:

- 1 Alice: if you imagine that the ducks in the beginning were land birds, and then some started to get web, and then it favoured them in swimming, and those who didn't have any web crawled onto land
- 2 Anna: they developed their own type of foot
- 3 Alice: exactly
- 4 Anna: then they developed because they needed it
- 5 Alice: no they who were webbed stayed in the water
- 6 Anna: and got more and more web
- 7 Alice: yes but not because they needed it
- 8 Anna: they develop it because
- 9 Amy: they can't think, I need that gene
- 10 all: no no
- /.../
- 15 Amber: I don't think that number one has to imply that now I need it and then I get it
- 16 Amy: not originated because it was needed but remained when it was needed in that case

As seen in this excerpt, the notion of need (in spite of its colloquial origin) plays an important role in the students' discussion and in turn 16 need is used in a rather sound scientific manner and the whole statement from Amy (16) is an example of using an interlanguage.

Theoretical and Educational significance of the research

The findings reported in this study make it possible to argue that colloquial expressions are not a hindrance in students learning; on the contrary they are a resource. Learning biological evolution encompasses both language and conceptual aspects: need, randomness, and development are important meaningful notions in reasoning and students develop their use. The notions get a scientific meaning in spite of their colloquial origin (cf. the notion 'need') and students have to enter the arena of interlanguage in order to connect colloquial and school scientific reasoning. Furthermore, students discern how colloquial and school scientific language on the one hand differs, and on the other could be kept together when discussing biological evolution. Language and conceptual aspects interact in intricate ways, and this paper hypothesize that the verbalisation in an interlanguage makes it easier to communicate in social life, outside the science classroom, and thus it increases the possibility of further learning.

PAPER PRESENTATION

Bilingual newspaper – a tool for multicultural education?

Roni Reingold, Achva-College of Education, Israel; Lea Baratz, Achva-College of Education, Israel

The aim of the current study is to analyze the discourse in a special newspaper, which is edited by the Israeli Ministry of Education and distributed among high school students, immigrants from Ethiopia. In Israel the Ministry of Education is a political agency which controls educational policy and practice throughout the country. Analyzing the discourse can help to examine and expose the formal and real educational policy. The newspaper is bilingual, written in Hebrew and in Amharic - the original language of the immigrants from Ethiopia. Preliminary, it seems as if the newspaper reflects pluralistic multicultural approaches, but deep content analysis of hundreds of articles revealed a different reality. The research reveals that there is no real multicultural attitude. Using the principals of critical discourse analysis (Gee, 1992, 2004; Van Dijk, 1991, 2001), we categorized the topics and the content (purposes) of the articles. Our findings are that the newspaper actually reflects an ethnocentric attitude of the editors or in other words implied an approach of assimilation. Thus; the multicultural cloak is actually a fake one. Never the less, in the voices of some of the members of the community of the immigrants themselves, there are some first signs of adopting a real multicultural attitudes.

Ethiopian Beta Israel community, comprising of more than 120,000 people, have immigrated to Israel under its "Law of Return", which gives Jews and those with Jewish origins, the right to immigrate to Israel and obtain citizenship (Ben Ezer 1992). The Ethiopian Jews' encounter with the Israeli experience exposed them to the process of socialization and acculturation. One of the obstacles that the Ethiopian society has to deal with as an immigrant society is the acquiring of a new language of the host country (Cohen & Spector, 2003). According to the structural functional attitude, language is a means for forming national identity (Menachem & Geijst, 1999), they did not have many formal opportunities to use their original language- Amharic Except among them inner milieu. Hence, when the Ministry of education begun, ten years ago, to publish and to hand to high school students, Ethiopian Jews, a bilingual newspaper it seemed as a tendency towards a multicultural education policy (Reingold, 2007). Bilingualism should be looked upon as an interdisciplinary area, including not only linguistics, but all behavioral sciences. According to Nevo and Olstein (2008) bilingual situations can be discerned: bilingualism or multilingualism is concerned with a few languages spoken in the home ground/environment (home or country); sequential bilingualism is concerned with acquiring a foreign language within the educational system, and acquired bilingualism as a result of immigration processes. On one hand a bilingual text can be a tool for acquiring the new language by having the graphic and parallel presentation of two languages side by side, and on the other hand it can be a means of emphasizing the fact that it is part of a process for preserving a language, indirectly aimed at preserving an ethnic identity.

Methodology

The principals of critical discourse analysis (Gee 1992, 2004; Van Dijk, 1991, 2001) served as the guidelines for deep content analysis of hundreds of articles in journals which were published revealed a different reality. Our purpose by using critical hermeneutics while categorizing the topics and the content (purposes) of the articles is to expose hidden power imbalances and challenges in the frame of the Israeli educational system. Findings Out of 169 articles which were published in the newspaper 60 focused on educational issues, 53 dealt with stories of personal success, 29 were about projects in the community, 24 about parents-children relationship and 3 about criminal activities and drug addiction in the community. In a lot of the articles there was use of the term excellence: "Excellency instead of criminality"; "Her three children are excellent students"; "How did you succeed to raise such an excellent children?"; "The excellent students will get stipend". In many articles there was a use of the term integrate or integration: "We should fully integrate in the Israeli society"; "We should integrate both in educational systems and society"; "If we will succeed in higher education programs we will succeed to fully integrated in the Israeli society". Never the less, in some of these articles the voices called for integrating the history of the Ethiopian Jews into the formal curricula.

Discussion

The story of the Beta Israel community, as it is being told in a bilingual Hebrew- Amharic newspaper, has a potential to help both the Ethiopian community members and the Native Israelis to accept the 'self' and the 'other' accordingly, to understand the significance of the individual within the social complex and to develop tolerance towards the other. In order to serve as such bilingually tool, words should not be used as a 'single voice' that represents the exclusive and hegemonic voice, but should represents a dialog among voices. Bilingual texts should actual be a demonstration of the term 'fruit salad' (Audrey, 1992), contrary to the grasps of the "melting pot" regarding hegemonic cultures that impose their essence over the 'other'. But in the current study we found that the Israeli Ministry of Education prefers not to use the potential of the bilingual Hebrew- Amharic newspaper as a tool for developing a dialog among voices, but rather to represents the hegemonic voice. Never the less, since the Ministry cannot fully control the voices; some voices of multicultural attitudes are becoming part of the discourse.

PAPER PRESENTATION

Stereotypes and their role in the educational careers of Turkish students in Germany

The paper presents an interview study that tried to explore if, how and to what extent students with a Turkish background in Germany experienced impairments from negative stereotypes during their school career. Although most of the respondents (N=15) denied in a general way that they were treated or judged according to stereotypes during their educational career, they recalled a series of specific episodes in which stereotypes came into play or were evident. Most of the episodes took place at transitional points, particularly at the transition from primary school to secondary schools and were associated with teachers' judgments. Students felt that they were not judged according to their individual capability but according to teachers' anticipated difficulties of minority students in higher education. Helpful for overcoming impairments seems to be a strategy of ignoring negative information, maintaining a positive self-concept, actively negotiating one's role and building upon a strong parental support.

Objectives and theoretical framework

When it comes to educational outcomes an achievement gap between immigrant/minority students and non-immigrant majority students is observed in many countries. In Germany this gap is particularly wide for students with a Turkish background (Stanat & Christensen, 2007). Different explanations have been proposed for understanding the causes of this under-performance. Some researchers point to the existence of group-specific stereotypes that may affect teachers' judgment and behaviour. Despite still sparse empirical evidence, existing studies make it plausible to assume that stereotypes play a (major) role especially in transitional phases. When teachers have to give recommendations for secondary schools and continuing education their judgment seems to be based on stereotypical knowledge (Alleman-Ghionda, 2006). Stereotypes may also account for expectancy effects of which students with a minority background are particularly likely to be negatively affected (Jussim & Harber, 2005). Research on stereotype threat reveals how existing stereotypes within a society undermine the academic success of minority students, even when their teachers do not share these stereotypes (Steele, Spencer & Aronson, 2002). Stereotype threat has a corroborated impact on members of many different types of groups and on their performance in varying domains (but has not yet been investigated for Turkish students in Germany). Research evidence, however, is almost exclusively based on experimental studies. It is still unclear whether these results can be generalized from the laboratory to classroom settings and whether or how this effect corresponds with students' subjective experiences. The proposed paper presents an interview study that tried to explore if, how and to what extent students with a Turkish background in Germany experienced impairments from negative stereotypes during their school career. This study focused students who successfully graduated from secondary schools. There were several reasons for restricting the sample to "successful" students: 1) According to stereotype threat research those with high educational ambition are particularly vulnerable to stereotype threat. 2) Those who succeeded in the given educational system despite the alleged impact of negative stereotypes may have developed particularly promising coping strategies. Furthermore, students at the end of a rather long schooling career may have gathered a wealth of experiences with negative stereotypes to report of, especially as they had to go through a series of transitional phases.

Method

Research questions. The following questions were addressed: 1. In as far and to what extent did students with a Turkish background in Germany experience impairments from negative stereotypes during their school career? 2. How did they cope with these experiences? 3. What factors proved to be supportive in overcoming impairments?

Design and Sample. Semi-structured, in-depth interviews were carried out with 15 students who had just successfully graduated from school and were about to enroll in university courses. Participants' age ranged from 22 to 32 years (M=25,7), nine of them were female and six were male students. All were second or third generation immigrants.

The interviews were retrospective and explorative in nature. Participants were asked to give an account on the course of their educational career. They were instructed to tell everything that came to their mind. Participants' knowledge and awareness of negative stereotypes in the society about their group was addressed explicitly by the interviewer.

Procedure and Analysis

The interviews were digitally recorded; verbal transcripts from the recordings were produced. Analysis was based on an inductive content analysis. The transcribed interviews were segmented into statements; these statements were assigned to identified themes and categories and interpreted as to the research questions. Two researchers categorized the subjects' statements independently. The categorizations were compared and discrepancies discussed until a consensus was reached. This procedure enabled the researchers to supplement and challenge each other findings, thereby strengthening the validity of the categories. The following main categories were developed 1) knowledge of stereotypes 2) personally meaningful episodes associated with negative stereotypes and/or experiences of discrimination 3) characteristics of reported episodes and situations (frequency, time, persons involved) 4) ways of dealing with relevant situations 5) sources of support.

Preliminary Results and Conclusions

Results so far indicate that all interviewed students are aware of negative stereotypes in the society. In their view existing stereotypes linked Turkish students' poor performance with innate competence deficiencies and with a specific value system of Turkish families. Although most of the participants denied in a general way that they were treated or judged according to stereotypes during their educational career, they recalled a series of specific episodes in which stereotypes came into play or were evident. Most of the episodes took place at transitional points, particularly at the transition from primary school to secondary schools and were associated with teachers' judgments. Students felt that they were not judged according to their individual capability but according to teachers' anticipated difficulties of minority students in higher education. Helpful for overcoming impairments seems to be a strategy of ignoring negative information, maintaining a positive self-concept, actively negotiating one's role and building upon a strong parental support. Specific support of German friends and teachers was also helpful for most of the respondents.

It may be concluded that stereotypes play an important role in Turkish students' educational careers, especially in the transition to secondary schools. Hence, the stereotypes Allemann-Ghionda (2006) identified in teachers' recommendations correspond to students' actual experiences. Awareness of stereotypes, however, seems to be gained in retrospective reflection and may not be given in the actual educational situation. The tendency to deny that they as individuals were judged or treated according to stereotypes can be regarded as defense mechanism; a view that is in line with stereotype threat research. Developing strategies of self-affirmation may help to overcome the psychological threat. This can be a starting point for possible educational interventions as the results of Cohen et al. (2009) indicate. To overcome this explorative study's limited scope ongoing research investigates differences between high and underachieving Turkish students' strategies and experiences.

PAPER PRESENTATION

Realities and Perceptions for Teachers of New Migrant Children in England

Naomi Flynn, University of Winchester, United Kingdom

Migration from Poland to the UK since 2004 has presented schools and teachers with a new set of experiences as they accommodate Polish children in their classrooms. Interviews with English teachers reveal that this has been a largely positive encounter because of their perception that Polish identity is characterised by aspiration and hard work. Contrasting interviews with Polish teachers whose pupils have left with their families in order to build a 'better life' in England, suggest that this rose-tinted view is based on some over-simplified assumptions that fail to engage with the reality for migrant workers and their children. This paper uses a Bourdieusian framework for analysis to interpret teacher response from both Eastern and Western Europe. Narrative interviews present divergent accounts of children's experiences that enhance current understanding of the ways in which migrant children cope with school and how they establish social and linguistic capital.

Schools in England have recently undergone a shift in their pupil demographic which reflects changing patterns of trans-European migration since the accession of new member states to the EU in 2004 and 2007 (DCSF, 2008). There is evidence that this shift is one experienced not just in inner-city schools most commonly associated with minority ethnic populations, but in a wide range of schools in rural and smaller town settings in a number of counties across the country (Gaine, 2007). Perhaps the most visible of migrants in the workplace and in schools are Polish nationals. In adjusting to new faces and new languages in their classrooms, teachers in areas not previously associated with national or ethnic difference are required to respond pedagogically and pastorally in ways not necessarily matched to their existing teaching repertoire. Such a change fosters experiences that will fuel these teachers' images of national differences, and these images will grow from a mixture of both their preconceptions about migration and their particular encounters with the families and children they work with.

The aim of this study is to compare teacher's responses and attitudes to Polish children in Primary schools in England with the perceptions of Polish teachers whose children have left their native country as part of the post-2004 cross-European migration. There is growing evidence that the migration of Eastern Europeans, particularly Poles, is somehow different from earlier waves of migration to the UK and the US (Favell, 2008). The new migrants have rights to work and to move freely within EU countries as European citizens and this makes comparison with Post-colonial theories of race, migration and ethnicity largely redundant (p.706). Studies of teacher response to difference come largely from the US and they focus on teachers working with pupils from Black or Hispanic backgrounds. There is very little research to date on how teachers, or other community members, respond to migrant families who are white and European. Research in to this recent phenomenon is needed in order that the teaching profession can be informed in its response to children's cultural and linguistic differences. Interviews were conducted with teachers in schools in the south of England at the beginning and end of academic years between 2007 and 2009. The schools were selected for

having admitted Polish children in the previous school year and because they had limited or no experience of receiving children from other countries. The conversations focussed on their pedagogical approaches to supporting their pupils' language acquisition, but coded analysis revealed a seam of thinking related to migration and, in particular, a range of very positive attitudes to Polish children and their families. The comparison interviews with Polish teachers in 2010 explored the reasons why Polish families might choose to come to England, and the impact of migration on their schools. Questions were designed specifically to query the reality behind English teachers' perceptions and positive attitudes to Poles. Coding of the interview transcripts used Bourdieusian constructs of field, habitus and capital to map how perception and reality in the teaching profession plays out in response to the unfamiliar. Applying an interpretivist approach supported by constructivist grounded theory (Charmaz, 2006) nodes clustered on teachers' responses to the children that rested on their pupils' classroom habitus as hard working and aspirational. English teachers' images of national differences appeared to grow from a mixture of both their preconceptions about the reasons for migration and their particular encounters with the families and children they worked with (Flynn, forthcoming). Thus teacher habitus, as governed by existing perceptions of minority ethnic children and their needs, triggered generalised views based on limited experience. Furthermore, these teachers' views of their children as attentive and studious meant cultural difference was minimised (Bennet, 1998). Perceptions bred realities that may or may not have been based on truths. Comparing the English teachers with their Polish counterparts, there were clearly elements of the narrative around migration from the Poles' point of view that were unseen and unknown in the field of the English classroom. Initial inspection of the data suggests that the experience of migration is more complex than Western Europeans might perceive for both the Polish families leaving Poland and for the schools and communities they leave behind. Interpretivist enquiry assumes that what we imagine is the truth is not an objective reality but is the result of our perceptions (Schwandt, 2000). Such perceptions grow unconsciously from habitus, and as such cannot adapt unless challenged explicitly. The cross-referencing of interviews from both the host and the donor nations allowed the researcher to consider where reality and perception might lie for Polish children and their English teachers. Moreover, it threw in to question the ways in which English education policy for new arrivals assumes oversimplified needs that do not take account of individual difference, and which do not require the dominant culture to look beyond conjecture. This research is significant because of the way that it presents a lens on a recent socio-cultural phenomenon using data from both Eastern and Western European perspectives. Furthermore, it explores the world of the classroom which has been hitherto under-represented in studies examining the new migration. Theoretically it enhances and broadens a small, existing body of work using a Bourdieusian framework to analyse classroom interaction (Grenfell and James, 1998; Christian and Bloom, 2004; Christ and Wang, 2008); it does this by looking at both social and linguistic capital in schools in the specific context of migration. The application of Bourdieu for analysing interview narrative reveals levels of behaviour and response that surpass literal interpretation and question assumed realities.

PAPER PRESENTATION

Exploring hurdles to immigrants' academic success in secondary education

Karolina Retali, University of Oxford, Greece

The last two decades large amounts of immigrants came to Greece, which led to a change of students' population. Schools in Greece have amassed a large number of immigrant students, mainly from Albania and the former Soviet republics. However, there is a lack of national, representative large-scale research on immigrant students' academic achievement in Greece. The present research consists of two main studies: In Study 1, differences between immigrant students' science achievement, as measured by PISA 2006, and their native-born counterparts' are examined and compared, and the potential effect of various factors on immigrant students' science performance in Greece is explored. Then, in Study 2, the key findings of Study 1 are explored and similar trends are sought in other 20 countries with significant immigrant population. Thus, the generalisability of the significant results from Greece is examined, in order to test the ecological validity of the conclusions.

An in-depth multilevel analysis was conducted, with fixed and random slopes models. Results showed that immigrant students in Greece performed significantly worse in science than their native-born counterparts. However, controlling for the language spoken by students at home eliminated the difference between immigrant and native-born students: Students who did not speak Greek at home performed worse in science. Similar trends were noted in the cross-national comparison. These findings point to a need for a stronger language support policy at schools.

Aim of the study

The last two decades, large amounts of immigrants came to Greece, which led to a change of students' population. Schools in Greece have amassed a large number of immigrant students, mainly from Albania and the former Soviet republics; a number that every year is increasing. However, there is a lack of national, representative large-scale research on immigrant students' academic achievement in Greece. Therefore, the present study focuses on the

differences between immigrant and native-born students in Greece and the relationship between various factors and immigrants' academic performance (Study 1). The key immigration issues found as significant in Greece are explored and similar trends are sought in 20 countries with significant immigrant constituencies (Study 2). An in-depth multilevel analysis of the PISA 2006 science data was conducted to address these issues, in order to get a better insight into immigrants' performance in Greek schools and to assist in the promotion of excellence and equity in the Greek education system.

Theoretical background

The overarching theoretical framework of the study is an eco-systemic approach based on Bronfenbrenner's (1979) ecological systems model. This approach argues that the variables examined in the study belong to various environments and levels, but are intertwined and influenced by each other, which provides a theoretical support to the models used in the analysis of the data. The cultural capital theory (Bourdieu & Passeron, 1977) is also central to the analysis of the data. The study looks at the extent to which family background characteristics influence academic achievement and whether there is evidence that socio-economic status (SES) can explain the differences among students as well as the differences among students from various ethnic groups. Issues of contextual effects of schools on students' academic achievement are also discussed (e.g. school-average SES, schools' educational resources).

Data

The present study uses Programme for International Student Assessment (PISA) database. PISA is a cross-sectional international assessment distributed by the Organisation for Economic Cooperation and Development (OECD) every three years, which consists of questionnaires aiming to assess not only students' knowledge on an academic subject but also their ability to use knowledge and skills acquired in reading, mathematics and science in everyday life (OECD, 2007). The Greek PISA 2006 data were used for the purposes of the Study 1, and consists of 4,873 students and 190 schools. 7.5% of the students included in Greek PISA 2006 are immigrants (weighted percentage). Study 2, the cross-national comparison, had a sample of 145,323 students, using data from 21 countries in PISA 2006 with significant immigrant population.

Methods used for analysis

Immigrant students' science achievement in PISA was scrutinised, with various individual, background and school factors included in the model. The database used in the present study was gathered taking into account that students are grouped within schools and therefore influenced by them, and thus it includes both individual and school level variables. Therefore, it was possible to perform a multilevel modelling analysis, which is considered the most appropriate method for the analysis of the associations of the independent variables with the dependent variable, as it is not overlooking the contextual effects. Thus, variances at different levels are separated and the different effects of individual and group level variables on the outcome variable are distinct (Gelman & Hill, 2006; Goldstein, 2003; Hox, 2002; Van de Vijver et al., 2008; Snijders & Bosker, 2004). Both random intercept and random slopes models were conducted.

In addition, the standardised final weights provided by PISA were used in the present study in order to account for the complex survey design of PISA and multiple imputation was used to deal with missing data in order to reduce the risk of biased results.

Results

Results of the analysis of the PISA 2006 Greek data showed that immigrant students performed significantly worse in science than their native-born counterparts. However, after controlling for language spoken at home, the effect of immigrant status was no longer statistically significant: Students who did not speak Greek at home performed worse in science. The actual language spoken at home (Russian, Albanian, other) did not make a difference as long as it was not Greek. Although controlling for various background variables decreased the effect of immigrant status on science achievement, it was the language spoken by students at home that eliminated the difference between immigrant and native-born students. This finding implies that a number of immigrant students in Greece do not have sufficient Greek language skills and therefore there is a need for a stronger language support policy at schools. In addition, another important finding of the present study regarding immigrant students' achievement is the fact that the effect of immigrant status on science achievement does not differ across schools. In other words, the difference in immigrant and native-born students in achievement is the same across schools. Furthermore, the age of immigrant students when they arrived in Greece showed that students that had arrived within the last four years before their science assessment were more disadvantaged than their immigrant counterparts that had lived longer in Greece. These effects did not vary with language spoken at home. The cross-national comparison showed similar trends.

Educational importance of the study

The present study analyses for the first time Greek PISA results in depth and provides an extensive report of factors associated with immigrants' science achievement in secondary education in Greece. Although causation cannot be implied, policy makers and practitioners can find valuable information in the described links among predictor factors and immigrants' academic success. Results can provide the basis for future longitudinal studies on immigrants' achievement and for discussion for future reform of different aspects related to immigrants' educational needs, such as student enrolment policies, language support and teacher training. Therefore, the present study provides useful information by extending the existing knowledge of factors associated with immigrants' academic achievement in Greek schools, as it uses an international assessment with large and representative sample of students from Greece and tests the ecological validity of the findings. This is essential in order to start understanding immigrants' educational needs in Greece and help the Greek education system provide immigrant students with equal chances to academic success.

PAPER PRESENTATION

Research projects in taught Masters programs and possible preparation for doctoral entry

Margaret Kiley, CEDAM, Australia

The aim of this project was to illuminate the poorly understood research education components of taught/coursework Masters programs. With a substantial increase in enrolments in coursework Masters in Australia and with a growing number of applicants seeking PhD entry with coursework Masters qualifications this project examined the extent to which a coursework Masters that includes a substantial research project, provides an effective, supportable entry to a PhD research program.

Given the extremes of variability in Masters programs e.g. one year to two years fulltime in length, and with a research project worth less than a quarter of the total credit to those worth up to one half, it is critical that we understand this variability and what it means for students, institutions and funding bodies.

The research indicates that the research experience of some coursework Masters students is such that they determine they want to undertake a doctoral program. Influences on these decisions include the rigour of the research component, the assessment criteria, the experience, training and expertise of staff supervising the research project, and an understanding the contribution and impact of the research project.

Aims

The aim of this project was to illuminate the poorly understood research education components of taught/coursework Masters programs (Trigwell, Shannon & Maurizi, 1997). With a substantial increase in enrolments in taught/coursework Masters in Australia and with a growing number of applicants seeking PhD entry with taught Masters qualifications this project examined the extent to which a taught/coursework Masters that includes a substantial research project, provides an effective, supportable entry to a PhD research program in Australia (Neumann, 2002, Pearson, Evans, Macquale, 2008).

Given the plethora of Masters programs with extremes of variability e.g. one year to two years fulltime in length, and with a research project worth less than a quarter of the total credit to those worth up to one half, it is critical that we understand this variability and what it means for students, institutions and funding bodies.

Methodology

Research on this question commenced in 2009 with research conducted in conjunction with the Australian Deans and Directors of Graduate Studies (DDoGS). The Deans, that is those University senior staff responsible for doctoral education, as a group were asked to:

- List the knowledge, skills and attitudes that you believe to be essential for entry to a PhD
 - In groups, collectively rank these from most important to least important
- Against each of the ranked characteristics/criteria note one or more ways in which an
- applicant could demonstrate these criteria in an application.

The second stage of the research was the collection of data on the variation of Masters programs where PhD applicants use coursework masters results as a PhD entry qualification. Data were collected at four publicly funded universities (one each from the Group of Eight, Australian Technology Network, and Innovative Research Universities groupings, as well as one regional university). The research aimed to identify the extent to which the research project in a taught/coursework masters is "experienced," as a research preparation program. Findings

The research indicates that:

- The research experience of some taught/coursework Masters students is such they determine that they want to undertake a doctoral program
 - Much of this decision making is based on the rigour, seriousness of the research component, and the assessment criteria adopted in the research project
 - Another factor in decision making is the experience, training and expertise of staff supervising the research project
 - Understanding the contribution and impact of the research project in taught/coursework Masters programs on the quality and nature of the learning experience and learning outcomes of graduates is critical. Theoretical and educational significance of the research
- Possible entry and exit points and curriculum structures that allow for variation in learning and professional experiences are still poorly understood. A particular urgency for this study was brought about by the global recession, given that previous experience suggests that there is a correlation between unemployment and increased enrolments in research degrees (Harman, 2002).

In particular the research provides insights into why Masters students' make the decisions that they do regarding doctoral study.

PAPER PRESENTATION

“Coming to this community was a great moment in my life” -Critical experiences during PhD process

Jenna Tuomainen, University of Helsinki, Finland; Kirsi Pyhalto, Helsinki University, Finland; Kirsti Lonka, University of Helsinki, Finland

Little is known about what drives the doctoral journey. What kinds of experiences make doctoral students keep up with this demanding process? This study explores the critical experiences during doctoral journey perceived by the students themselves. Nineteen doctoral students from natural sciences were interviewed. The interviews were content analyzed by using a phenomenography inspired strategy. The turning points described by the doctoral students were situated in various academic activities, such as conducting field measurements, attending to courses, participating in conferences and publishing articles. Within these situations the doctoral students emphasized the importance of participation in the scholarly community, such as becoming a member of their own research community and getting to know the international field. They also highlighted the significance of their development as a scholar, in terms of constructing motivation and strengthening views of efficacy. In addition, the doctoral students considered advancements in research and in domain specific knowledge and skills including advancements in working with and knowing of instruments as important. Moreover, they described the importance of balancing between different requirements, for instance, combining own research and other academic assignments. In all these four categories the majority (84%) of turning point experiences were described as positive or promoting. In doctoral students' experiences, other things besides advancement in knowledge and skills were commonly mentioned. In natural sciences, the critical experiences were often related to becoming an acknowledged member of the scholarly community and perceiving oneself as a scholar. Such experiences were reported in relation to common academic activities.

Introduction

Little is known about what drives the doctoral journey. What kinds of experiences make doctoral students keep up with this demanding process? This study explores the critical experiences during doctoral journey perceived by the students themselves.

Students' experiences of their doctoral process are central regulators for their learning as a scholar. These experiences reflect interpretations and choices students make, and thus, experiences define, for instance, what students perceive as a goal and how they interpret feedback. This way the experiences contribute to students' learning.

Doctoral experiences include different kinds of dimensions. Recent research has explored some of these dimensions, for instance, doctoral students' experiences of their academic identity (McAlpine & Amundsen, 2009), research work (Meyer, Shanahan & Laugksch, 2005) and socialization (Gardner, 2007). However, little is known what students perceive as critical experiences during their doctoral journey.

Aims

The aim is to identify 1) the critical experiences during doctoral journey perceived by students, 2) in what kinds of activities the experiences are situated perceived by students, and 3) how the experiences contribute to the doctoral process perceived by students. This study is a part of a national research project on doctoral education in Finland.

Doctoral studies in natural sciences context

Characteristic of doctoral education in natural sciences is collective and international training in research communities and shared projects (Cumming, 2009) as well as pursuing a thesis based on co-authored articles. Thus, the scholarly community provides a collective mechanism for supervision.

Methods

This study included data collected from an internationally acknowledged research community in a large research intensive Finnish university. Altogether, nineteen doctoral students (female: 10, male: 9) from natural sciences were interviewed. The critical experiences were explored through key events (a.k.a. critical incidents, Tripp 1994). In the semi-structured interviews the participants were asked to visualize and point out key events as well as explain what they were.

The data were content analyzed by using a phenomenography inspired strategy. Thus, the analysis was driven by the data and the focus was on variation in the described experiences. First, all the text segments where the participants referred to significant turning points were coded in the same category. Then, the turning points were coded according to the primary context of the experience: research work, PhD studies, academic meetings, supervision, publishing, academic assignments, and personal activities. After this, the turning points were coded in four exclusive categories according to general meaning given to the experience as perceived by the participants: participation in the scholarly community, development as a scholar, advancements in research and in domain specific knowledge and skills, and balancing between different requirements. Finally, the key events were coded in two exclusive promoting and hindering categories as perceived by the participants.

Findings

The doctoral students reported a variety of situations ranging from attending to study courses to conducting research work. They emphasized experiences varying from encouraging leaps in understanding promoting satisfaction and enthusiasm to problematic situations, for instance, tensions in supervision causing insecurity and anxiety. Moreover, they reported both long episodes as well as short events.

The key events described by the doctoral students were typically situated in various academic activities. The students described research work (24%), such as conducting field measurements and working with new projects. They reported also their PhD studies (19%) including attending to courses and recruitment. In addition, the students described academic meetings (15%), such as participating in conferences as well as their supervision (15%), for instance, having new advisors. Furthermore, they also reported publishing (13%), such as writing and getting articles accepted, and academic assignments (10%) including teaching. Moreover, few of the events were situated to students' personal activities (4%), such as having sabbatical free.

Within these situations the doctoral students emphasized the importance of participation in the scholarly community (35%). They highlighted becoming a member of their own research community, meeting international researchers as well as mismatch in a supervisory relationship. The students also described the significance of development as a scholar (29%). Especially, they described becoming interested in their domain, struggling with ambiguous image of the doctoral process as well as strengthening views of their efficacy and future intentions. In addition, the students emphasized the significance of advancements in research and in domain specific knowledge and skills (29%). They often brought out advancements in working with and knowing of instruments as well as understanding their research object. Furthermore, the students described the importance of balancing between different requirements (7%), for instance, combining own research and other academic assignments.

In all these four categories the majority (84%) of the experiences were described as promoting. Advancements in perceptions of oneself as a scholar, understanding the domain as well as participation in the scholarly community were considered as constructive and supporting progress. In contradiction, for instance, inadequate supervision and

problems with instruments were considered as destructive and leading students to struggle with interruptions in their research.

Theoretical and educational significance

In doctoral students' experiences, other things besides advancement in knowledge and skills were commonly mentioned. In natural sciences, the critical experiences were often related to becoming an acknowledged member of the scholarly community and perceiving oneself as a scholar. The results demonstrate that the critical experiences in doctoral students' lives take place in the context of quite ordinary academic activities. Supporting the growth of a doctoral student appears to lie in reflecting on everyday practices from an educational perspective.

PAPER PRESENTATION

Developing employability skills of doctoral researchers: exploring students' perceptions

Elena Golovushkina, Glasgow Caledonian University, United Kingdom; Colin Milligan, Glasgow Caledonian University, United Kingdom

Past few decades have seen an increased interest in the issues of graduate employability including that of doctoral researchers. The purpose of this paper is to address the gap in the literature and explore the views of doctoral researchers on the employability and skills development issues. The paper details the views of researchers on three aspects of employability: the concept of employability and its meaning for doctoral researchers; employability skills that doctoral researchers expect to develop; and their awareness of employers' expectations. Based on the literature review, research questions have been designed to explore the perceptions of social science doctoral researchers on the issues of employability. Semi-structured interviews have been conducted with 15 full-time PhD students in various social science disciplines at one of the Scottish universities. Initial findings suggest that there is a link between the initial motivations of doctoral researchers to do a PhD degree and their views on employability. The data provides an insight into doctoral researchers' perceptions the understanding of the skills that PhD graduates expect to develop during candidature. The results of the interviews pose questions for further debate on the skills formation at the PhD level. Paper provides a valuable insight into the under researched area of employability of doctoral researchers.

Graduate employability has been the focus of much activity at both research and policy levels within Higher Education. Initially focused primarily on undergraduate students, in the past few years the debate has broadened to include the development of employability skills of postgraduates, including doctoral researchers. Interest in this area is further enhanced by the large number of doctoral researchers pursuing careers outside academia. For example, a recent report produced by the UK Royal Society (2010) indicates that 53% of PhD graduates are employed in the sectors outside academia. These figures are confirmed by the Vitae report "What do researchers do?" (2010) that shows that more than a half of UK doctoral graduates are employed outside academia across the commercial, government and non-for-profit sectors. An emphasis on the range of employment destinations challenges a traditional understanding of a PhD as a degree leading to the employment in academia. In these conditions one of the priorities of Higher Education Institutions is to seek ways of transforming "students into highly proficient, independent researchers, capable of adapting to a range of employment destinations and taking up positions in academe, industry and the professions" (Manathunga 2007, p 19).

The diversity of career paths of doctoral researchers poses important questions about the skills that PhD candidates should develop to be successful in their chosen occupations later on. Previous attention in this area has been focused primarily at policy and practice level. For example, one of the biggest initiatives in this area in the UK was introduced by the Research Councils that developed the Joint Skills Statement (2001) - a set of skills that Research Councils-funded postgraduate researchers are expected to develop during their candidature. As a result, this framework was adopted by many UK universities for providing transferable skills training for researchers. Past few years have also

seen a growing body of research literature outlining the current discussion on the formation of professional researchers and their employability skills (Cryer 1998, Gilbert et al 2004, Manathunga et al 2009). Despite an increased focus on this aspect of doctoral education, discourse in this area still lacks studies exploring perceptions of doctoral researchers themselves on their employability and the key skills they need to develop.

In an attempt to address this gap, this paper provides an insight into the perceptions of social science doctoral researchers on the concept of employability and development of employability skills. The paper details the views of researchers on three aspects of employability: the concept of employability and its meaning for doctoral researchers; employability skills that doctoral researchers expect to develop; and their awareness of employers' expectations. Perceptions of doctoral researchers were investigated by means of exploratory semi-structured interviews. The questions used in the interviews were devised on the basis of the relevant literature review as well as the data obtained from the analysis of the secondary data. Semi-structured interviews have been conducted with 15 full-time PhD students in different social science disciplines at one of the largest Scottish universities. Social sciences disciplines were selected based on the list of disciplines provided by the UK Economics and Social Research Council. The participants have been recruited using a mixed sampling technique. The findings represent the first phase of data collection on exploring the perceptions of doctoral researchers and other stakeholders in Scottish Higher Education Institutions on development of employability skills and the ways we can enhance employability of social science doctoral researchers.

The initial findings suggest that there is a link between the primary motivations of doctoral researchers to do a PhD degree and their views on employability and future career aspirations. The majority of students interviewed expressed an intention to pursue a career in academia upon graduation. This largely determines their understanding of their employability skills and the expectations of employers. For example, when asked what are the 3 things that PhD students need to do to be employable upon graduation, the activities cited most frequently by respondents were 'publishing research papers' and 'teaching'.

The views of participants related to requirements of the employers were also largely determined by their pursuit of an academic career. Another important finding relates to the PhD candidates' perceptions of their learning and how they develop employability skills. The majority of researchers acknowledged the important role of everyday tasks they are involved in, and stated that they develop various skills by engagement in these tasks. Only few researchers mentioned that they develop these skills by attending the skills workshops provided by the university. These perceptions are closely related to the concept of situated learning where learning is acquired in the context of its application (Lave & Wenger 1991). However, one of the biggest challenges of situated learning is its transferability to other contexts. This poses further questions for development of skills of doctoral researchers that can be transferred to different contexts (Greeno et al 1996). These findings potentially may also have some implications for a wider agenda of employability skills development of researchers and the impact of the skills training.

The study contributes to the body of knowledge on development of employability skills of doctoral researchers in social sciences. It also provides the ground for further exploration of the perceptions of PhD candidates on the skills development during candidature.

PAPER PRESENTATION

An early-stage Personal Development & Planning course to engender effective self-management in PhD s

Sofie Kobayashi, University of Copenhagen, Denmark; Sine Grumloese, Roskilde University, Denmark; Brian Grout, University of Copenhagen, Denmark; Camilla Osterberg Rump, University of Copenhagen, Denmark

This study seeks to examine the lasting benefits of an induction course developed to support new postgraduate students in becoming 'self organising agents' and managers of their own personal and professional development. A cohort of course participants were interviewed 18 months after they participated in the course, and the study shows that 50% of respondents continue to use tools and methods provided at the induction course, and that the course had supported them significantly to take charge and manage their own learning environment. This paper describes the rationale behind the course design based on a theoretical grounding in situated learning in communities of practice, and concludes with suggesting seven essential elements of the course: Self perception, Meeting PhD students as whole persons, Personal Development Planning – working with them, Intercultural, Safe haven - 5 days off campus residential, Inclusiveness – sense of belonging, Managing relationship with and reducing distance to supervisors. The study confirms that viewing research education in terms of situated learning, using a pedagogy which mobilizes the resources of the research (learning) environment, can support the development of PhD students to become self organising agents and enable them to take up opportunities available in their environment.

Introduction

The Faculty of Life Sciences at the University of Copenhagen (LIFE) has experienced a dramatic increase in PhD students over the last 10 years, and with this follows the challenges of increased diversity among PhD candidates. This calls on new pedagogies for educating researchers, and we set out to design an induction course based on own and reported experiences: Phillips and Pugh (1994) advise PhD students that supervision and research should be 'under your own management' (p. 2). Grant and Graham (1999) attempt to empower PhD students by introducing strategies for more effective self management, including learning journals, project planning, time management and goal setting. Cryer (1998) has developed guidelines for developing 'transferable skills'. The Quality Assurance Agency (QAA, www.qaa.ac.uk) in the UK provides guidelines for personal development planning (PDP). Boud and Lee (2005) challenge the prevailing institutional approach to supervisor training and provision of rich research environments, and advocate for new pedagogies in research education to enable students to take up opportunities that are available, as self-organising agents in a broader learning environment. Especially Boud and Lee's work inspired our design of the course, which aims at supporting new PhD students in becoming 'self-organising agents'. We designed an optional, 5-day residential Introduction Course at LIFE in 2007. Two courses were held in 2007 and growing interest has resulted in five courses in 2010 with an ongoing waiting list. However, despite very positive evaluations little is known about its lasting effects. We did not know if the students went on to use what they learnt on the course during the remainder of their study, and we did not know if they retained the feelings of ownership and empowerment that we hoped for.

Aims

The aims of this qualitative study is to identify lasting benefits of our induction course to enable us to make general recommendations for induction courses in higher education, and to develop our course further. Methods Twelve PhD students who participated in an Introduction Course in 2008 took part in qualitative research interviews conducted according to an interview guide with a clear purpose and structure controlled by the interviewer as described by Kvale and Brinkmann (2009). There is a continuous condensation of meaning during the interview, and this condensation continues in analyzing the material. To gather information about the respondents' professional lives, the interviewer asked questions in three areas: Had they used, and did they still use, any of the personal management tools and strategies introduced at the course? Did they view themselves as having a significant level of influence over their PhD process, and had any feeling of empowerment that the course provided been sustained? Did they regard themselves as people with a high level of self-management control in their professional lives?

Findings

According to the respondents the elements of the course with most impact were: understanding how to construct and use a Personal Development Plan meeting other PhD students to share cultural diversity and build networks being met in an acknowledging way A number of the participants recognised the PDP as part of the empowering process and talked of it as providing tools to help structure the PhD process. I still use it, I think it is a good way to think about the process. (...) in the PDP you write more about your skills and also other things, which are not related to your PhD so therefore I think that it is a good way to keep it to write on, that there are some professional things and theories I need to know about. (...) I update my PDP every six months and I have added new points (Man 1) Respondents acknowledged the importance of being recognised as more than "just a PhD student" and, potentially, as a 'researcher in charge', and saw it as a part of their empowerment. These guys are lecturers and they supervise PhD students so if they know that I am not just a PhD student but that I am a person then it actually makes it better for you as a student. This guy knows that I am a person! It is good that he knows that I am a person then I also see myself as a person. (Woman 1) The study gives evidence of the value of using the PDP tools particularly in the beginning of the PhD study. The participants all completed a PDP, which was discussed with their supervisor. Two years later half of the PhD students still use this tool and describe it as a part of their ability to be in charge.

Conclusions

The qualitative study clearly shows that our introduction course does exactly what Boud and Lee (2005) suggest: We enable PhD students to take charge and make use of the learning opportunities available in the broader research environment. Our course is different from what is offered most other places in the ways we meet and work with PhD students, their self perception and their collaboration with supervisors. The very high level of lasting benefits from the course proves that our approach is right.

PAPER PRESENTATION

Effective Teaching and Learning in Higher Education

Sabine Hoidn, Harvard University, Switzerland

This paper provides an overview of three major strands concerned with the effectiveness of teaching and learning in higher education. The paper is based on an extensive literature review and brings research findings from (1) process-outcome research, (2) information-processing concepts of teaching effectiveness and (3) constructivist instruction and the creation of effective learning environments together. Reviewing the literature it might be useful to synthesize and align the research from these different strands to apply an increasingly holistic perspective. Based on the evidence found in research studies and meta-analyses in each strand implications for effective learning and teaching in higher education will be outlined.

This paper provides an overview of the effectiveness of teaching and learning in higher education. It is based on a literature review and brings research findings from the following three strands together to draw implications from these findings for higher education.

(1) Process-outcome research

In the 1970s studies on instructional or teacher effectiveness became influential and researchers tried to determine important factors to improve teacher effectiveness. Process-outcome research helps to understand what effective teaching is, why it is effective, and how it impacts student learning and development. The process-outcome definition of effective teaching is concerned with the link between process and outcome – between what teachers do and whether and how students change as a result. In this paper I will introduce Marsh's (1987; Marsh & Dunkin, 1997) nine, Feldman's (1989, 1997) twenty-eight and Abrami, d'Apollonia and Rosenfield's (2007) four factors/dimensions on teaching effectiveness as well as Murray's (1997, 2007) low-inference teaching behaviors to outline the state-of-the-art in research on instructional effectiveness based on process-outcome research.

The review indicates that the following three dimensions emerge consistently as strong predictors of diverse instructional outcomes: Enthusiasm/Expressiveness, Clarity of Explanation and Rapport/Interaction. However, additional theoretical thinking is necessary to learn more about cognitive processes of students as well as about effective teaching processes. An increasing emphasis on student-centred learning in higher education has made traditional forms of student ratings based on lecture-style courses and lower-level educational objectives questionable to judging teaching effectiveness.

(2) Information-processing concepts of teaching effectiveness

In the course of the cognitive revolution the focus began to shift to instructional activities that support cognitive processes involved in knowledge building. The teacher makes decisions and judgments on basis of a multitude of variables and it is assumed that good teaching leads to student learning. For example, the teacher plans the lessons taking students' background such as motivation and prior knowledge into account and adjusts his teaching strategies accordingly. Research suggests connections between effective instructional dimensions and cognitive information-processing concepts (Mayer, 1987; Murray, 1997, pp. 181-183): Enthusiasm factors can serve to elicit and maintain student attention to material presented in class due to elements of spontaneity and stimulus variation. Attention is crucial for all information processing and research indicates that students are more likely to pay attention to teachers who exhibit expressive behaviors. Clarity factors facilitate meaningful encoding (e.g. structured outlines of the subject matter), connection to prior knowledge (e.g. through concrete examples) and storage in long-term memory in the course of information processing. Interaction factors encourage active student participation in the classroom and allow students to actively engage in all stages of information processing. From this point of view teaching is regarded as helping students to store information and knowledge in long-term memory.

Ramsden (2003) condensed research findings based on the cognitive tradition into six principles for effective instructors:

- (a) Interest and explanation (quality of explanation and stimulation of student interest)
- (b) Concern and respect for students and student learning (interest in and compassion and consideration for students)

- (c) Appropriate assessment and feedback (helpful comments on students' work, quality of feedback on students' progress, appropriate assessment tasks)
- (d) Clear goals and intellectual challenge (high academic expectations, clear structure focused on key concepts, provide interesting challenges)
- (e) Independence, control and engagement (student choice and control over learning and interest in the subject matter)
- (f) Learning from students (openness to change)

(3) Constructivist instruction and the creation of effective learning environments

Constructivist pedagogy is a way to help students learn so that they can construct knowledge and develop meaning and deep understanding based on their prior knowledge while interacting with their material, social and cultural environment (Richardson, 2003). However, so far there is a lack of a sense of effective constructivist teaching and this is in part due to the lack of a constructivist teaching theory. Thus, constructivist teaching often defines itself by what teachers should not do compared to the cognitive transmission model (e.g. "Do not tell!"), for example (Fenstermacher and Richardson, 2000). Constructivists suggest that learning does not only depend on cognitive processes but also on social interactions, participation in a community and other processes leading to a contemporary understanding of cognition as distributed and learning as essentially "contextualized". Hence, a change in knowledge stored in long-term memory as a result of learning is not enough (cognitive theory). The same was true for sole changes in visible behavior (behaviorist theory).

Research on constructivist teaching has largely focused on the description of the constructivist teacher who thinks, beliefs and acts in a way consistent with a constructivist philosophy rather than on effective teaching. Research has shifted from laboratory-based experiments towards real-life classroom situations. There are many case studies that describe exemplary constructivist teaching (often compared to traditional teaching); however, there is scarcely research that describes "effective" constructivist teaching, and the measurement of learning outcomes and factors that affect them is less developed (Fenstermacher & Richardson, 2000). Up to today, there is a lot of stimulating rhetoric for the constructivist position, but only a slim empirical research base supporting constructivist instruction (Tobias & Duffy, 2009). One exception is the extensive research base on problem-based learning, for example.

Overall, there is a vast literature on effective teaching and scholars from different research fields and strands work in this area – often without connecting and building upon each other's work. Reviewing the literature it might be useful to synthesize and align the research from different strands to apply an increasingly holistic perspective. Based on the evidence found in these three major research strands implications for effective learning and teaching in higher education will be outlined.

PAPER PRESENTATION

Pedagogical Models for Developing Work Life Skills in Higher Education

Paivi Tynjala, University of Jyväskylä, Finland; Seija Nykanen, University of Jyväskylä, Finland; Anne Virtanen, University of Jyväskylä, Finland

The purpose of the study is to identify pedagogical models for developing generic skills in academic education. Data were collected from six courses in three Finnish universities. Data included 1) group and individual interviews with teachers, educational developers, heads of departments and other staff members (altogether 10 interviews with 33 interviewees) 2) student questionnaires in three of the courses (N=163, n=123), and observations of two courses. Data analysis is based on the mixed methods approach. Three tentative models for organising the development of work life skills have been identified: 1) Specialist/Centralised Model, 2) Distributed and Integrated Expertise Model, and 3) Cultural Networked Model. In the Specialist/Centralised Model the connections between education and work are taken care of by specialists, while in the Distributed Model all teachers and staff are involved in developing collaborative networks with the outside world. Characteristics of the Cultural model are a holistic approach to competence development and the planning and coordination processes of the whole institution. The following characteristics were also identified: 1) Collegial and collaborative working culture 2) Instructional design based on theory, 3) Holistic planning 4) Integration of theoretical, practical and self-regulative knowledge, and 5) Positive atmosphere. Furthermore, all courses were based on long-span development. Students reported that in these courses they had learnt domain-specific skills, collaboration and communication skills, and situational sensitivity or working creatively and proactively in different situations.

Rapid changes in society pose urgent challenges to higher education. It is recognised that in addition to providing students with deep domain-specific academic knowledge, education must provide them with the skills to cope with continuous change and an uncertain future. As a consequence, higher education institutions have increasingly paid

attention to the development of skills that go beyond content knowledge and are often described as transferable skills, generic capabilities, generic skills, or key skills. It has also been noticed that although these skills seem to be transferable from one situation to another, they still have a domain specific character (e.g. Jones, 2008). Therefore it has been suggested that they should be developed as integrated into domain knowledge rather than taught in separate courses (e.g. Bowden et al., 2000).

The purpose of the present study is to identify pedagogical models for organizing higher learning in a way that academic goals and generic skills are given equal emphasis. In more detail, the following research question is addressed: what kind of pedagogical models higher education institutions have devised for developing the kind of skills and competencies needed in the world of work? Theoretically, identifying promising pedagogical practices is based on the idea of integrative components of the development of professional expertise (Tynjälä, 2008), the model of learning by developing (Raj 2007) and the notion of constructive learning environments (e.g. Biggs 2003; Tynjälä, 1999; Tynjälä et al. 2009).

Data were collected from six courses in three Finnish universities (one of which is a university of applied sciences). Three of the programs were selected on the basis of student questionnaire where students were asked to name a study module which, in their experience, had best developed their generic skills and increased their knowledge about the world of work. Other three were selected on the basis of previous studies on work-related learning in higher education (e.g. Vyakarnamet.al. 2008; Tynjälä et al., 2009). Data included 1) group interviews and individual interviews with teachers, educational developers, heads of departments and other staff members (altogether 10 interviews with 33 interviewees) 2) student questionnaires in three of the courses (N=163, n=123), and observations of two courses. Themes of the interviews were: 1) skills needed to perform successfully in the world of work 2) activities of the educational organization to develop work life skills; 3) networking within the educational organization and with the world of work 4) guidance and 5) evaluation and development. The questionnaires included questions about students' perceptions of their learning environments and learning experiences. The observations were carried out using a coding scheme that focussed on the features of constructive learning environments (e.g. Biggs 2003; Tynjälä et al., 2009) and a model of integrative pedagogy (Tynjälä, 2008).

Data analysis is based on the mixed methods approach. Questionnaire data and quantitative observational data are being analysed with quantitative methods, while the interview data and qualitative observation data is being analysed by qualitative content analysis adopting abductive approach. Thus, data-driven and theory-driven analyses interact in the analysis.

So far, our analyses have produced the following preliminary findings. Three tentative models for organising the development of work life skills have been identified: 1) Specialist/Centralised Model, 2) Distributed and Integrated Expertise Model, and 3) Cultural Networked Model. In the Specialist/Centralised Model the connections between education and work are taken care of by specialists, while in the Distributed Model all teachers and staff are involved in developing collaborative networks with the outside world. Characteristics of the Cultural model are a holistic approach to competence development and the planning and coordination processes of the whole institution. The following characteristics were also identified in courses that were successful – as assessed by students - in developing generic skills: 1) Collegial and collaborative working culture 2) Instructional design based on theory, 3) Holistic planning 4) Integration of theoretical, practical and self-regulative knowledge, and 5) Positive atmosphere.

Furthermore, all courses were based on long-span development. The teachers were in close interaction with the world of work. Therefore, it was flexible for them to work in the interface of theory and practice. Students reported that in these courses they had learnt domain-specific skills, collaboration and communication skills, and situational sensitivity or working creatively and proactively in different situations. Thus, the learning outcomes differed from those of more traditional university courses in which skills of knowledge acquisition and working independently have been reported as most important outcomes (e.g. Virtanen & Tynjälä, 2010). Final results will include theoretical models of 1) the development of work life skills, 2) networking and 3) leadership and management of educational institutions in developing students' work skills (cf, Nykänen 2010).

PAPER PRESENTATION

Evaluation of an Entrepreneurship Education Course for Students

Karin Heinrichs, Goethe-University in Frankfurt, Germany

In line with other entrepreneurship education courses the so called 5-Euro-Business-Competition intends to foster entrepreneurial intentions and to offer students various opportunities to gain experience in creating and realizing an entrepreneurial opportunity. Therefore this program represents a modern Entrepreneurship Education: Students are not only taught about entrepreneurship. They learn how to deal with real problems in forming and running a new venture and are coached how to solve real problems.

This paper presents an evaluation study of this voluntary 5-Euro-Business-Course. On the one hand the study assessed the selection effect of this voluntary course. On the other hand we asked whether the treatment really had a positive effect on fostering entrepreneurial intentions as expected. So we tested whether the participants of the course gained more in entrepreneurial intention than the control group and had a higher increase in the predictors of forming an entrepreneurial intention. In order to answer these questions we conducted a quasi-experimental study with pre- and posttest. The results show remarkable effects.

Beyond that effects on strengthening entrepreneurial intentions we think that this program may also foster growth in personal determinants of entrepreneurial success in the post-formation phase (e.g. experience-based knowledge in coping with critical incidents or self-regulation strategies), which is planned to be investigated during the next term evaluation.

Theoretical framework and aims of the study:

Today more and more modern Entrepreneurship Education concepts do not only teach about entrepreneurship. They change to a more active way of learning and provide students opportunities to develop context-specific knowledge, entrepreneurial skills, attributes and behavior. They foster competencies to recognize entrepreneurial opportunities as well as to solve problems which are quintessentially for the phase of forming a new venture (Kickul & Fayolle, 2007, p. 2; Kirby, 2007, p. 21-24). They offer the participants the chance to gain experience in authentic situations and to reflect this experience.

The 5-Euro-Business-Competition, which has been conducted at different German Universities for 10 years, can be considered as such a modern learning concept. During this voluntary course students of various faculties are coached in forming a new venture within only one term. The participants got the chance to increase be coached in performing a start-up process (BBW & Hochsprung, 2010). The organizers presume that this course will help to encourage the participants to form entrepreneurial intentions. Referring to the Planned-Behavior-Theory therefore it would be important to foster positive attitudes (attractiveness) towards entrepreneurship as well as to develop perceived behavior control (as an aspect of feasibility, e.g. context-specific self-efficacy and entrepreneurial knowledge (Krueger & Casrud, 1993). The question is if these objectives can be reached during only one term and if they, can they be achieved by engaging in the 5-Euro-Business-Competition.

On the one hand we know from previous research that entrepreneurial intentions really can be developed in student programs, especially in courses fostering active and experience-based learning (Walter & Walter, 2008, p. 562). On the other hand we know from an evaluation of a compulsory course that particularly these students stand to benefit from entrepreneurship education who have already started at a high level of entrepreneurial intention. However, those

participants who started at a low level of entrepreneurial intention, tended to decrease in their motivation to form a new venture (Graevenitz, von, Harhoff & Weber, 2010).

But what are the effects of this Entrepreneurship course "5-Euro-Business" due to entrepreneurial intentions? The effects of this competition were evaluated in the presented study.

Research Questions:

1. Is the competition more attractive to persons with high or with low entrepreneurial intentions and perceived behavior control? (Effect of Participant Selection)
2. Do the participants show an increase in the entrepreneurial intention and in perceived behavior control more than the control group does?

Methodology

Design and Sample:

We chose a quasi-experimental design with

- (a) an experimental group (participants of the Entrepreneurship Competition in summer 2010 and a control group (students of different faculties of the University of Frankfurt) and
- (b) a pretest as well as a post test. So we contrasted students having attended Entrepreneurship Education course and those having not.

Instruments:

The relevant personal determinants we measured by common tests:

- a. Entrepreneurial intention (Davis, 2002),
- b. Entrepreneurial self-efficacy (de Noble, 1999),
- c. Entrepreneurial prior knowledge (Shane, 2000).

In addition we gathered some basic demographic data like gender, age or field of study.

Results

1. The participants of the competition differ in the pretest from those of the control group in entrepreneur-specific personal determinants significantly in entrepreneurial intentions (high effect: $d=0,8$), domain-specific self-efficacy (middle-sized effect: $d=0,59$) and prior knowledge (small effect: $d=0,29$). The program is apparently more attractive to students who already think entrepreneurship to be attractive and feasible.
2. The participants of the competition differ in their growth of entrepreneur-specific personal determinants compared to the control group significantly. They seem to benefit from the course in the intended way: prior knowledge in entrepreneurship ($p=0,001$; high effect: $d=0,85$), entrepreneurial self-efficacy ((tendency: $p=0,007$; small effect: $d=0,36$).

Theoretical and Educational Significance

The results confirm that entrepreneurship courses can foster personal determinants which are relevant for forming an entrepreneurial intention even if the treatment lasts only 2-3 months. We actually found powerful effects. However, the evaluation is restricted to determinants which are supposed to explain the way to form such an intention. It would firstly be very helpful to get information about the sustainability of the increased intentions. Secondly we plan to assess learning outputs which are crucial particularly for solving entrepreneurs' problems not on the way to form an entrepreneurial intention, but to cope with the problems in the post-formation phase: the ability to assess and solve critical incidents which may emerge during the first years.

PAPER PRESENTATION

Students' approaches to learning in six different Bachelor study modules

Liisa Postareff, University of Helsinki, Finland; Telle Hailikari, Faculty of Behavioural Sciences, Dept of Education, Finland; Sari Lindblom-Ylänne, University of Helsinki, Finland

Research focusing on changes in approaches to learning of individual students in different study modules is missing, while approaches to learning at group level have been studied more often. The present study aims to analyse the changes and differences in approaches to learning described by students at the beginning and at the end of Bachelor level study modules in two different disciplines. Specifically, the aim is to analyse how individual students describe change in their approaches to learning in one or more study modules. The results showed at group level, that in two of the six study modules, there was a statistically significant change in the deep approach scale, while in three study modules there was a statistically significant change in the surface approach scale. In five study modules, the change in the organized studying approach scale was statistically significant. Preliminary results imply, however, that there are differences in how individual students describe change in approaches to learning within one study module and between different study modules. More fine grained analysis of individual change in learning approaches will be conducted to identify different types of combinations of changes in approaches to learning. The results deepen our understanding of the stability or changeability of approaches to learning of individual students and are useful in developing university teaching and learning environments.

Introduction

The studies concerning the context specificity of approaches to learning have had contradictory results. According to Liez and Matthews (2010) science students' approaches to learning are relatively stable whilst Rodrigues and Cano (2007) found approaches to learning to be changeable. In addition, studies concerning the context-specificity of approaches to learning in different study modules have been scarce. Furthermore, studies indicate that some students tend to change their approaches to learning more easily during their studies while other students approaches to learning are more stable (Lindblom-Ylänne, 1999). The aim of the study is to analyse the differences in approaches to learning described by students at the beginning and at the end of Bachelor level study modules. Specifically, the aim is to analyse how individual students describe change in their approaches to teaching within one study module and between different study modules.

Method

A total of 293 bachelor students participated in the study. Of these, 199 students participated in one, two or three Bachelor level (mainly second year) study modules at the faculty of Biological and Environmental sciences, and 94 students participated in one, two or three study modules at the faculty of Behavioural Sciences, University of Helsinki. All the study modules, except for one, were lecture type modules, the number of students varying from around 40 to 100. One study module was a different type of course, in which the students had a very active role in regulating their own studying. At the beginning of the study module the students filled in a short version of the Approaches to Learning and Studying Inventory (ALSI), including 16 items in which students were asked to describe how they usually study during a course unit or module (Entwistle & McCune, 2004). At the end of the study module the students filled in the ALSI again, but they were instructed to describe how they have studied during that particular study module. In addition, the students filled in an 21-item version of the Experiences of Teaching and Learning Questionnaire (ETLQ; Entwistle, McCune & Hounsell, 2002) modified to the Finnish context. The students were asked to respond to the items using the 5-point Likert scale (1=agree to 5=disagree).

Analysis and results

Factor analyses using Maximum Likelihood extraction with Varimax rotation were carried out. The items describing approaches to learning constituted a three factor solution: Organised studying, Deep approach and Surface approach. Based on this, sum scales of the three approaches were created. A paired samples t- test was used to analyse the significance of the change between the two measurements on students' approaches to learning. In two of the six study modules, there was a statistically significant change in the deep approach scale, while in three study modules there was a statistically significant change in the surface approach scale. In five study modules, the change in the organized studying approach scale was statistically significant. The shift in the three approaches to learning from the typical approach students usually apply, described at the beginning of the study module, to the course-specific approach, described at the end of the study module, was further analysed by computing 'change variables' for each approach. This was done by subtracting the students' approach scale scores when they were describing their typical approaches at the beginning of the study module from the scores when describing the course specific approaches. The students' change scores on the three approaches from the usual approaches to the course specific approaches varied. The change in the deep approach scores varied from -1.38 to 1.50, for the surface approach from -2.5 to 2.00 and for organized studying from 1.00 to 2.75 on the 1–5 point scale. Negative values indicate that the scores of the approaches were higher at the beginning of the study module than at the end of the study module. Conversely, positive scores indicate that the scores of the approaches were lower at the beginning of the study module than at the end.

There was variation between the study modules in the change variables on the deep and surface approach scales. Two of the three study modules at both faculties resulted a positive change, i.e. a decrease in the deep approach scale and a negative change, i.e. an increase in the surface approach scale. On the contrary, one study module at both faculties resulted a negative change, i.e. an increase in the deep approach and a positive change, i.e. a decrease in the surface approach scale. All six study modules resulted a decrease in the organized studying approach scale. Preliminary results imply that individual students describe changes in different approaches within the study modules they have participated in very different ways. Some students describe an increase in both deep and surface approaches, while others describe changes in opposite directions. In addition, some students do not describe changes at all, or describe changes only within one approach. Furthermore, some students describe similar changes in approaches in all study modules they have participated, while others describe different types of changes between different study modules. More fine grained analysis will be applied in investigating changes of individual students. Students' experiences of their teaching and learning environment will be analysed to find out how they are related to possible changes in approaches to learning.

Theoretical and educational significance

The results deepen the understanding of the stability or changeability of approaches to learning. Specifically, research focusing on changes in learning approaches of an individual student in different study modules is missing, while approaches to learning at group level have been studied more often. The results help to identify direction and magnitude of changes within individual students in approaches to learning and help to recognise different types of learners. In addition, the effect of the teaching-learning environment on approaches to learning in different study modules help to identify which specific factors in the environment have an effect on how students study and learn. The results are valuable in developing university teaching and learning environments and in helping different types of learners to cope with their university studies.

PAPER PRESENTATION

The Effects of Autonomous Learning on Cognitive Load and Learning Results

Chantal Gorissen, Open University of the Netherlands, Netherlands; Liesbeth Kester, Open University of the Netherlands, Netherlands; Saskia Brand-Gruwel, Open University, Netherlands; Rob Martens, Open University, Netherlands

This study concerns the effect of autonomy when studying learning material on students' motivation, perceived mental effort and learning results, taken into account students' prior domain knowledge, learning ability and attitude towards learning. The study is situated in the area of instruction design. Research about cognitive load has shown noteworthy implications for instructional design. However, how to foster the active use of available cognitive load through instructional design is still debated. Motivation may be considered an important aspect. Consulting Self-Determination Theory, fostering motivation through instruction design would mean more learner autonomy. A total of 95 grade 5 students studied material about volcano's and earthquakes. The setup was a between subjects design with three conditions. In the first condition (fixed procedure) students worked their way through the study material in a predetermined way. In the second condition (learner control) the students had to choose their own study material from a database, no structure was provided. In the last condition (autonomy) the students got control over the type of control for each task, by being able to choose their own study materials (condition two), follow the structured learning

path (condition one), or creating a mix of the two. The data has been collected, the analysis is still in progress, but are expected to be final by the end of this year.

Introduction

Research in the area of the Cognitive Load Theory (CLT) (Sweller, 2003; Van Merriënboer & Sweller, 2005) has, in the past, mainly focussed on reducing extraneous load on working memory. How to stimulate germane load, the load on working memory from processes that contributes to learning, is still debated. One way of stimulating germane load is thought the improvement of motivation (Paas, Tuovinen, Van Merriënboer & Darabi, 2005). Paas and Van Merriënboer (1994a), already concluded that the design of instruction to optimize cognitive load on working memory, is only useful when the learner is willing to invest the mental effort that is required. We introduce the motivation perspective of Self-Determination Theory (SDT), which focuses on control and self-directedness of the learner, as this plays a major role in hypermedia learning environments. From the SDT-perspective, adding autonomy to a learning environment seems the most appropriate way to improve motivation through instruction (Katz & Assor, 2007; Ryan & Deci, 2006). This means that the learner has a certain amount of control. Research on learner control has shown that control can have positive effects on motivation (Corbalan, Kester & Van Merriënboer, 2009). However, there are many inconsistent results and according to Skinner (1996) there is little consensus about what types of control are beneficial or harmful for motivation and learning, and how learner control interacts with certain learner and situational characteristics. Autonomy and learner control differ on the level on which the learners receive control. Autonomy provides control on a higher level compared to learner control. In an autonomy supportive environment, learners also control the type of control for a learning task, and can therefore choose not to choose. Autonomy supportive environments enable learners to obtain or maintain an autonomous type of motivation. Which, according to SDT, causes more deep-level learning strategies (Grolnick & Ryan, 1987; Vansteenkiste, Lens, & Deci, 2006), leading to more in-depth understanding in contrast to memorized facts, and more curiosity and explorative behavior (Martens, Gulikers & Bastiaens, 2004). The aim of this study is to examine the effect of autonomy when studying learning material on students' motivation, perceived mental effort and learning results, while taken into account students' prior domain knowledge, learning ability and attitude towards learning.

Method

Participants A total of 95 grade 5 students (49 male, mean age 10.72) participated in this study. The experiment was setup as a project and took place in the regular school environment of the participants. **Set-up** The set-up of this study is a quasi experimental between subjects pre-test post-test control group design, with three conditions. All students were presented with the same short essay questions on volcano's and earthquakes, which they had to answer using video material. The conditions differed in the type of control students had when working their way through the material. In the first condition (fixed procedure) students worked in a predetermined way. In the second condition (learner control) the students had to choose their own study material from a database, no structure was provided. In the last condition (autonomy) the students got control over the type of control for each task, by being able to choose their own study materials (condition two), follow the structured learning path (condition one), or creating a mix of the two. Participants worked 4-8 hours individually with a digital hypermedia learning environment on a computer. Before working with the tasks the participants prior knowledge and general regulation style was measured. After each essay question the participants rated their cognitive load and enjoyed of the task. Afterwards, the students' learning results were measured twice, by two different types of tests (one to measure factual knowledge and one to measure in-depth understanding), once immediately following the tasks and again after 3 months. Following the learning result measures the type of motivation the students had for the tasks was measured, together with the satisfaction of their basic psychological needs scale (as proposed by SDT). Learning ability of the participants was indicated by the CITO (Central Institute for Test Development)-scores from each student, provided by the school. Log files recorded which video's were watched per task, as well as time per task.

Results/ Discussion

The collecting of the data was completed on the 25th of October 2010. The data analysis is still in progress, but are expected to be final by the end of this year.

PAPER PRESENTATION

A long and winding road – on requirement of a critical approach in self-regulated work

Anders Eklof, Kristianstad University, Sweden

Assessed, independent, creative and connected. The demands on students doing assessed self-regulated work are extensive. They are supposed to produce texts that require them to master a variety of competences. The capacity to exercise source criticism and the ability to think critically is considered to be substantial competences in these modes of work.

In this article we examine how secondary schools students relate to demands concerning criticism of sources and critical thinking. The students are studied in situations where teachers and tutors are not physically present. Drawing on Goffman's frame analysis and socio-cultural risk theory we discuss how different apprehensions on "what's going on" correlates with estimations on potential dangers connected with choices that has to be made. Different laminations of frameworks are put in play which can be related to an overall notion of an opaque and ubiquitous regime of assessment. In looking at dilemma situations, analysing different ways of framing, we will try to illuminate and understand obstacles students experience connected with demands for source criticism and critical thinking in self-regulated work. If the students' handling of demands placed upon them in some ways can be questioned in relation to a critical approach, we claim that what can be seen also can be described as a rational adaptation to a different framing on what school and education really are about.

The empirical material has been drawn from video recorded sessions where students are participating in collaborative writing. Our data consists of 60 hours of video filmed interaction collected over a three year period. The filmed interactions were then merged with films of screen activity and analyzed in Transana.

Assessed, independent, creative and connected. The demands on students doing assessed self-regulated work are extensive. They are supposed to produce texts that require them to master a variety of competences such as genre knowledge, different writing skills, ability to value and to make use of a number of institutional resources. Especially the capacity to exercise criticism of sources and think critically is considered to be substantial competences in self-regulated work.

The strive towards more individual work and the potential challenges this entails for education are discussed among others by Carlgren (2000, 2006) and Eriksson (2009). Granstrom (2003) shows that individual based teaching methods, in Sweden, have increased from 22% in the 1960s to 41% in the 2000s, while whole class teaching during the same period has decreased from 60 – 44%. Carlgren (2006) sets the amount of individual work as high as 50 % in 2003. This tendency towards a more individualized organization of teaching space coincides with a more general trend in late modern society requiring each individual to design and govern his/her own life (c.f. Bauman, 2000, 2002; Giddens, 1990, 1991). The increase of self-regulated work and the need to develop competences to find, evaluate and use different sources can also be seen in the light of how resources are used in "everyday life research" which might affect the educational outcome. Skills and competences developed in everyday settings can collide with skills and competences aspired in more formal educational settings. There are indications that students find searching and evaluation more difficult in educational settings than in "everyday life research" (Head & Eisenberg, 2009). Different forms of online activity and potential educational implications of increased peer collaboration are discussed among others by Mizuko (2008). New forms of authority emerges from the life on the net, something that has to be

considered in relation to the demand for criticism of sources and critical thinking connected with different forms of self regulated work.

The concept of critical thinking has been of major concern in educational science at least since the sixties when Ennis (1962) first published "A concept of critical thinking". In the light of the growth of self-regulated work and the special emphasis that is placed on critical aspects, there is a need for investigating how individualization, self-regulation and the impact of non-institutional learning strategies influence students work with source criticism and critical thinking in assessed situations.

In this article we examine how secondary schools students relate to demands concerning criticism of sources and critical thinking. The students are studied in situations where teachers and tutors are not physically present. Drawing on Goffman's (1974) frame analysis and socio-cultural risk theory (Lupton, 2000) we discuss how different apprehensions on "what's going on" correlates with estimations on potential dangers connected with choices that has to be made. We show how different laminations of frames interact and how these can be related to an overall notion of "doing being independent" and an opaque and ubiquitous regime of assessment. In looking at dilemma situations, analysing different ways of framing, we will try to illuminate and understand obstacles students experience connected with demands for source criticism and critical thinking in self-regulated work. If the students' handling of demands placed upon them sometimes are questioned in relation to a critical approach, we claim that what can be seen also can be described as a rational adaptation to a different framing on what school and education really are about. The empirical material has been drawn from video recorded sessions where students are participating in collaborative writing. Our data consists of 60 hours of video filmed interaction collected over a three year period. The filmed interactions were then merged with films of screen activity and analyzed in Transana.

PAPER PRESENTATION

Studying primary school children's self-regulated learning

Sabrina Vandeveld, Ghent University, Belgium; Hilde Van Keer, Ghent University, Belgium

Notwithstanding the fact that self-regulated learning (SRL) is an important educational goal and the call for promoting SRL early in students' school careers, only little research has been conducted on primary school children's SRL. This empirical lack is related to the current need for valid measures of SRL regarding this age group. In order to gain more insight in primary school children's SRL, the present study focuses on the development and validation of a comprehensive self-report questionnaire. Based on the conceptual framework of Pintrich (2004), the Children's Perception of Self-Regulated Learning (CP-SRL) questionnaire, consisting of 9 subcomponents, was developed. After constructing the items for each subcomponent, the items were reviewed by a teacher and expert panel. Further, cognitive interviews were conducted to establish cognitive validity. The 108-item questionnaire was presented to 504 fifth and 463 sixth graders. After exploratory factor analyses on each subcomponent, the factor structure of each subcomponent was confirmed by confirmatory factor analyses. Further, internal consistency was computed. The

results of these analyses indicate that the CP-SRL is an appropriate instrument for assessing SRL in late primary school children. As the instrument comprises several subcomponents, a differentiated view of children's SRL can be obtained. Therefore, the CP-SRL can be considered as a valuable tool to evaluate SRL interventions as well.

Relevance and objective

Self-regulated learners can be defined as metacognitively, motivationally, and strategically active participants in their own learning (Zimmerman, 1990). Research indicates that learners, who analyse task demands, set goals for their learning and then attempt to monitor and regulate their cognition, motivation, and behaviour experience more success in different learning situations (Zimmerman, 2002). Although self-regulated learning (SRL) is considered as an important educational goal (Boekaerts, 1999), research indicates that a large number of learners encounter difficulties regulating their learning efficiently and effectively (Perry, Phillips & Dowler, 2004; Zimmerman, 2002). Perry et al. (2004) highlight the importance of promoting SRL already in primary education. In order to foster SRL within this age group, it is however important to gain more insight into the self-regulatory processes primary school children engage in. Theoretical and empirical background Research reveals that primary school children are capable of acquiring self-regulatory skills (Veenman, Van Hout-Wolters, & Afflerbach, 2006). Notwithstanding these findings and the call for promoting SRL early in students' school careers (Perry et al., 2004), only little research has been conducted on young children's SRL (Winne & Perry, 2000). This empirical lack is connected to the current need for valid measures of young children's SRL (Winne & Perry, 2000). In order to enable large-scale research on primary school children's SRL, a comprehensive self-report instrument is wanting. Unlike most existing assessment methods restricting SRL to learning or metacognitive strategies, the self-report should comprise the different components of SRL. In this respect, Pintrich (2004) has developed a conceptual framework to assess SRL. This framework contains four areas of regulation: cognition, motivation, behaviour, and context. Within each domain, there are four phases referring to goal setting and planning, monitoring, control and regulation, and reflection. In this way the framework reflects the phased structure of SRL processes and the multi-component character of SRL.

Research goals

The aim of the present study is to develop and validate a comprehensive self-report questionnaire to gain insight in primary school children's self-regulated learning in academic contexts.

Research method

Participants 504 fifth and 463 sixth graders from 43 Flemish (Belgium) primary schools participated. Instrument Based on the framework of Pintrich (2004), a self-report questionnaire was developed. Taken into account the current literature and the fact that primary school children are the target group, 9 subcomponents were selected (see Table 1). For each subcomponent items were constructed, resulting in a pool of 108 items. The items were reviewed by an expert panel to establish content validity and by a teacher panel to determine the suitability for primary education. Finally, cognitive interviews with fifth and sixth graders (N=15) were performed to assess the cognitive validity of the self-report items (Karabenick et al., 2007). Based on the panel finding and cognitive interviews, the items were refined. The items were scored on a 5-point Likert scale. Data Analysis First, exploratory factor analyses (EFA) (maximum likelihood with promax rotation) were carried out to investigate the underlying structure of the items of each subcomponent. In order to determine the number of factors to retain, parallel analysis was used. Second, confirmatory factor analyses (CFA) were conducted on each subcomponent examining the stability of the exploratory factor structure. Finally, internal consistency (Cronbach's α) was computed.

Results and discussion

Regarding 5 subcomponents, both the parallel analysis and EFA suggest a one-factor model. With regard to the subcomponents 'self-efficacy', 'learning strategies', and 'self-evaluation' the analyses show a two factor solution. In line with self-determination theory and based on the parallel analysis and EFA four factors were retained for the 'motivation' subcomponent. Table 1 presents the results of the CFA, reliability analyses, and descriptive statistics. The CFA's show a moderate to good fit and the internal consistency was satisfying. The results indicate that the Children's Perceptions of Self-Regulated Learning (CP-SRL) questionnaire can serve as a valuable tool to assess SRL in late primary school children. In this respect, the development of the CP-SRL is of theoretical and empirical importance, since instruments measuring children's SRL are scarce. As the questionnaire comprises several subcomponents, it allows teachers and researchers to obtain a differentiated view of children's self-regulatory abilities and to evaluate SRL interventions. Additionally, it provides possibilities to explore the interrelationships among the self-regulatory subcomponents, leading to further theory development and testing. As the literature points at the importance of a multi-method approach to measure SRL (van Hout-Wolters, 2009), a combination of the present CP-SRL with concurrent methods (e.g. think aloud measures and trace methodologies) is advisable. Therefore, our current research focuses on the coherence between the self-report questionnaire, a task-specific questionnaire, and a think-aloud

protocol. The results of this follow-up study will also be discussed and related to the results of the present study during the presentation of the paper.

PAPER PRESENTATION

The growth in learning patterns during higher education: a latent growth curve model

Liesje Coertjens, University of Antwerp, Belgium; Vincent Donche, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium; Sven De Maeyer, Antwerp University, Belgium

Whether learning strategies change during higher education is increasingly investigated. To assess this, paired-samples t-tests or repeated measures ANOVA are primarily relied upon. Methodological literature has described two pitfalls concerning these statistical methods: first, only average growth is estimated and second, measurement error is unaccounted for. Recently, latent growth curve modelling has been described, allowing to model individual difference and to take into account measurement error. This study thus aims to estimate longitudinal change in learning strategies, using a latent growth curve analysis. The sample consists of one cohort of bachelor students, 245 of which participated in the three measurement waves by filling out the Revised Inventory of Learning Strategies (R-ILS), a self-report instrument mapping students' processing and regulation strategies. A curves-of-factors latent growth model is used. Such analysis estimates a growth trajectory by an intercept and a slope and estimates the variance in both parameters as well. Preliminary results indicate a significant increase in critical processing, relating and structuring as well as self-regulation during higher education. Memorising, external regulation and lack regulation decrease significantly, while analysing remains constant. For all scales, students vary in their initial level at the start of higher education, while no significant differences in growth trajectory were noted. Results from prior research are thus partially confirmed and supplemented with findings on individual differences.

Aims

A growing number of research has been investigating whether and how student learning strategies evolve during higher education. Vanthournout et al. (2010) therefore conducted a systematic review on longitudinal research using Vermunt's learning pattern model and derived Inventory of Learning Styles (ILS) questionnaire. The authors concluded that during higher education students predominantly evolve towards a more meaning-oriented way of learning and away from an undirected pattern, though effect sizes point on average to a small to moderate impact. In the majority of ILS-studies external regulation and stepwise processing (memorising and analysing) remained stable, pointing to high resilience to change. In analysing this change in learning strategies during higher education, statistical analysis has relied primarily on comparisons of mean factor scores over time using paired-samples t-tests or repeated measures ANOVA (Vanthournout et al., 2010). Two statistical pitfalls of these techniques are often noted in methodological literature. On the one hand traditional statistical methods only estimate average change in learning strategies. Individual differences in growth are unaccounted for. Such individual differences can for example be estimated using a multi-level approach (Singer & Willet, 2003). On the other hand, the use of this traditional statistical approach assumes absence of measurement error. By aggregating the scores on different items in composite factor scores, it is de facto presumed that items perfectly measure a certain learning strategy. Such error is however explicitly estimated in structural equation modelling (Byrne, 2010). Recently, a combination of both multi-level and

structural equation modelling has been described, being latent growth curve modelling (Duncan, Duncan & Strycker, 2006). While this statistical method is applied with increased frequency in other social science domains (e.g. De Fraine, Van Damme & Onghena, 2007), it has not been used before within longitudinal research of student approaches to learning to our knowledge. This study thus aims at estimating longitudinal change in learning strategies, using a latent growth curve analysis. Hereby, we focus on the average growth trajectory learning strategies show, as well as whether there are individual differences in this growth trajectory.

Methodology

One cohort of students entering a University College was followed up during the three years of higher education. 254 students participated at three measurement waves by filling out the Revised Inventory of Learning Strategies (R-ILS). This questionnaire maps four processing strategies (memoring, analysing, critical processing and relating & structuring) and three regulation strategies (external regulation, self-regulation and lack of regulation), using a five-point likert scale. Analysis consists of a curves-of-factors latent growth model as described by Duncan, Duncan and Strycker (2006) to assess change in learning strategies. Such analysis incorporates the items underlying a scales and estimates a growth trajectory by an intercept and a slope. To investigate individual differences, the variance of both parameters is estimated as well. Analyses were performed using Mplus 5 and relying on a distribution free estimation procedure to account for the ordinal nature of the data (weighted least squares means-variance; WLSMV). Findings Preliminary results indicate a decreasing reliance on the memorising strategy during higher education ($B = -.094$, $SE = .029$, $pB = .381$, $SE = .090$, $pB = .013$, $SE = .043$, $p = .77$), indicating that all students follow the general linear decrease. The level of analysing on the other hand remains constant over time ($B = .002$, $SE = .027$, $p = .95$), though students vary in their initial reliance on it ($B = .319$, $SE = .069$, p). Linearly increasing trends were confirmed for the degree of 'critical processing' and 'relating and structuring' ($B = .108$, $SE = .025$, $pB = .059$, $SE = .025$, $pB = .183$, $SE = .064$, $pB = .204$, $SE = .059$, p). The two scales 'external regulation' and 'lack of regulation' show similar trajectories as well: student decrease their reliance on these strategies during higher education ($B = .087$, $SE = .026$, $pB = -.127$, $SE = .023$, $pB = .158$, $SE = .064$, $pB = .173$, $SE = .051$, p). The self-regulation scale on the other hand shows a positive growth trajectory ($B = .106$, $SE = .030$, $pB = .259$, $SE = .083$, $pB = .026$, $SE = .040$, $p = .51$).

Theoretical and educational significance of the research

Results confirm prior research findings only partially. An increase in meaning directed learning was confirmed by the increase in critical processing, relating and structuring and self-regulation. The decreasing reliance on unregulated learning is in line with the findings of former ILS-studies (for a review, see Vanthournout et al., 2010). The high resilience to change in stepwise processing was however only exemplified in the analysing strategy, while significant decreases were noted in the reliance on memorising and external regulation. Additional to the general trajectory, individual variations in growth were examined. Results indicate that for all scales, students vary in their initial level at the start of higher education, while no significant differences in growth trajectory were noted. Future analysis will include latent class growth analysis and estimates of effect sizes for slopes parameters.

PAPER PRESENTATION

Overcoming the summer drop in reading: testing a localised intervention

Stuart McNaughton, The University of Auckland, New Zealand; Rebecca Jesson, University of Auckland, New Zealand; Tone Kolose, The University of Auckland, New Zealand; Sophie Kercher, The University of Auckland, New Zealand

A study in two phases was designed to overcome the summer learning effect (SLE), where drops in literacy achievement occur over summer. The effect reduces the effectiveness of schools with minority children from low SES communities. Initially, variability in SLE in 77 classrooms in 7 low SES urban primary schools was plotted for 2009 to 2010. High SLE and low SLE classrooms with 9-11 year old Maori (indigenous) and Pasifika (Pacific Islands) students were identified ($n = 16$). Interviews were conducted with high and low SLE students in each classroom ($n = 32$), their parents and their teachers to identify family, school and personal practices associated with SLE patterns. Teachers in low SLE classrooms more often prepared students specifically rather than just generally in four areas. Low SLE students and their parents more often reported interest based reading within and across genres, with parents responding to and providing guidance for reading for meaning and enjoyment. In the second phase a multi component intervention was designed using Phase 1 analyses and tested in a quasi experimental design across 25 classrooms over the 2010-2011 summer. The components include matching students with texts and a four week unit to prepare students in reading strategies, metacognition, and engagement; and specific guidance to parents. Teacher logs, student and teacher questionnaires provide measures of implementation. HLMs and repeated measures analyses of variance using reading comprehension scores provide comparisons across consecutive summers and comparisons between high and low implementing teachers

The presence of 'summer learning effects' (SLEs), where there is differential growth in learning over the months when schools are closed has been identified in a number of studies (Cooper, Charlton, Valentine, & Muhlenbruck, 2000; Entwisle, Alexander & Olson, 1997). Students from poorer communities and minority students often make less growth than other students over this period contributing to a widening gap in achievement. The SLE creates a barrier that gets larger over time (Alexander, Entwisle & Olson, 2007). Three intervention studies in reading comprehension involving over 50 schools serving largely Maori (indigenous) and Pasifika (Pacific Islands) students confirm the extent of the effect captured in previous research in New Zealand (McNaughton & Lai, 2009).

The SLE has been related to family social and cultural practices that provide differential exposure to school-related literacy activities (Cooper et al., 2000; Heyns (1978). The developmental processes involved mean that both schools and families (Anderson et al., 1988) may vary in providing access to and use of specific practices.

Two sorts of interventions that have been tested. One set adds resources in 'book flood' interventions such as Allington and McGill-Franzen's (2009) study with 17 high-poverty schools. Primary students selected their own books covering a range of topics and types to read over summer. The intervention produced reading growth compared to a control group that received no books that equalled the effect size Cooper et. al. (2000) reported in their meta-analysis for attending summer school. Other studies employ a programmatic approach, adding components to providing matched books. Kim's (2006) study with fourth grade children and their teachers in 10 high poverty schools added teacher preparation and guidance for students' independent reading and metacognitive development before summer with personally matched books. In addition, there were prompts to students and parents for 'read alouds' over summer. The programme produced relatively small gains relative to students who only got the teacher preparation and guidance. But the gains appeared to be sufficient to overcome the drop over summer.

Existing studies are not 'contextualised' for New Zealand. For example, it is not known whether access to books and guidance is a problem in the New Zealand context or whether classrooms practices and teacher guidance may be used in ways that might make a difference. The aim of the study was to firstly describe the variability in SLE and school, family and student practices associated with this variability. Then secondly to design and test an intervention using features of school and family practices associated with little SLE.

Methods and Results

Phase One

Growth curves using repeated measures of reading comprehension of 1,495 students in 7 multicultural low SES urban primary schools were plotted over 2009 to 2010. Variability in classrooms (n=77) over the summer break was used to identify two sets of classrooms of 9 year olds to 11 year olds: those associated with little SLE (n=8) and those with large SLE (n=8). A high SLE and low SLE student in each classroom (total n= 32) matched on achievement levels were interviewed together with their parents and their teachers about the practices within schools and their communities over summer. Quantitative analyses included coding teacher interviews in four areas of general or specific focus in preparing students for reading over summer (child strategies, child metacognition, child engagement and parental guidance). Teachers in low SLE classrooms more often prepared students specifically rather than just generally in the four areas (a finding supported by student and parent interviews). Most students and their parents reported a wide range of reading using multi media but low SLE students and their parents more often reported interest based reading within and across genres, with parents supporting access to texts, responding to and providing guidance for reading for meaning and enjoyment (rather than as homework, or for decoding).

Phase Two

From these data an intervention was designed with 3 major components. The classroom components include a survey of reading student interests, matching student interests with texts and a four week unit prior to the summer break focussed on preparing students (in the areas of strategies, metacognition, and engagement). The second component is specific guidance to parents about how to support engagement, and how to access and help children select texts. The third component will be a review session at the commencement of the new school year in February 2011. Teachers in 25 classrooms are implementing the programme with 9 year olds to 11 year olds (n=25). Teachers are filling in logs during the unit to provide a measure treatment integrity. Students and teachers will complete questionnaires at the end of the summer to provide self report (student) measures of student and family reading practices over summer and to provide social validity measures relating to the programme as implemented (teachers).

A quasi experimental design has been adopted for testing the effects of the intervention. Three sets of comparisons will be made using Hierarchical Linear Modelling and repeated measures analyses of variance. The comparisons firstly will be retrospective, comparing the patterns of gains (and losses) across classrooms in the 2010 to 2011 summer with those from the previous summer. A second retrospective comparison will be the patterns over the two summers for a

subset of teachers, those with large SLE in the previous summer. The third analysis will examine variation within the group of teachers using the teacher logs to directly compare high implementers with low implementers.

This study will contribute to solving a compelling educational problem. School effectiveness is limited by the cumulative effects of SLE. In addition, the data from this study will help our understanding of how family / community practices and school practices each contribute to continued learning and development in literacy over the summer break.

PAPER PRESENTATION

The understanding of written and spoken text of children from diverse language backgrounds

Selma Babayigit, University of the West of England (Bristol), United Kingdom

The study set out to examine the understanding of written and spoken text of monolingual and bilingual speakers of English language. Seventy two monolingual and bilingual pupils ($M = 10.01$ years, $SD = 0.42$) were tested at Year 5. Along with reading and listening comprehension of text, children's verbal memory, general reasoning, receptive vocabulary, and syntactic awareness skills were also assessed. As anticipated, oral language skills (i.e., vocabulary and syntactic awareness skills) emerged as the most powerful unique predictors of children's written and spoken text comprehension levels even when individual differences in general reasoning, verbal memory, and word reading skills were taken into account. There was also evidence to suggest that more bilingual learners were likely to experience difficulties in text comprehension that seemed to be associated with the weaknesses in semantic and syntactic processing of oral language. Hence, the overall results echoed the previous findings in this area of research (e.g., Lesaux, Lipka, & Siegel, 2006) and further signified the pedagogical implications of systematic support of the oral language skills of children from diverse language backgrounds.

The number of pupils who speak one or more language other than English (or the mainstream language of the schools) at home is increasing steadily. According to a recent report, 16% of primary school pupils speak English as an additional language in the UK and this is increasing by about 1% each year (SFR, 2010). There is now a substantial body of corroborating research evidence to suggest that while bilingual pupils perform at comparable levels with their monolingual peers on the measures of word level reading, they tend to underperform on the measures of text comprehension (e.g., Droop & Verhoeven, 2003; Hutchinson, Whiteley, Smith, & Connors, 2004; Stuart, 2004). The bilingual pupils' difficulties with text comprehension have been associated with weaknesses in oral language skills, such as vocabulary (Lesaux, Geva, Koda, Siegel, & Shanahan, 2008). However, the research in this area remains to be highly limited. The current study sought to further examine to what extent bilingual pupils experience text comprehension difficulties and the role of two central oral language skills, namely vocabulary and syntactic awareness skills in understanding of spoken and written text of bilingual and monolingual learners. This line of research has clearly important implications for developing our understanding of language and literacy needs of children from diverse language backgrounds.

Seventy two pupils ($M = 120.12$ months, $SD = 5.07$) at Year 5 were tested. Thirty five children were monolingual (i.e., spoke only English at home) and 37 were bilingual learners (i.e., spoke at least one language other than English at home). Children who have been attending a primary school in the UK less than four years and those with learning difficulties were excluded from the study. Thereby, it was ensured that bilingual pupils were not in the early stages of learning the English language, and that all children had adequate word decoding skills. The two language groups did not differ in terms of the distribution of age, $t(70) = -.48$, $p = .63$, or sex ratio, $\chi^2(1, N = 72) = 0.05$, $p = .82$. The home languages spoken by the bilingual learners in this study were Serbian (5, 14%), Arabic (4, 11%), Urdu (6, 16%), Somali (14, 38%), Bengali (2, 5%), Bulgarian (1, 3%), Sylheti (1, 3%), and Punjabi (4, 11%).

The children were tested individually at their schools over two sessions each lasting for about 25 minutes. The testing battery included the measures of general (matrix) reasoning, receptive vocabulary, reading comprehension, verbal short-term memory (digit span), syntactic awareness, and listening comprehension skills. With the exception of verbal memory, reading accuracy, and reading speed, the monolingual group scored reliably higher than the bilingual group on the general reasoning, oral language and comprehension measures and the effect sizes were large. Hence, the findings replicated the previous research and suggested that more bilingual learners tend to experience difficulties with oral language processing and text comprehension in comparison with their monolingual peers.

Following from this, a series of hierarchical multiple regression analysis was conducted to examine the predictive role of vocabulary and syntactic awareness skills in text comprehension levels. As anticipated, receptive vocabulary and syntactic skills emerged as the most powerful unique predictors of both reading and listening comprehension levels even when individual differences in general reasoning, verbal memory, and word reading skills were taken into account. The findings also suggested that the predictive effect of oral language skills were comparable between the

two language groups. In conclusion, the finding further echoed the call for a concerted effort on the close monitoring and supporting of children's oral language skills that seem to be even more vital for children from diverse language backgrounds (e.g., see Kamhi, 2009; Snow, Barnes, Chandler, Goodman, & Hemphill, 1991).

PAPER PRESENTATION

Phonological awareness, oral language proficiency and early reading in Hong Kong Chinese preschooler

Susanna Siu-sze Yeung, The Hong Kong Institute of Education, Hong Kong; Carol Chan, The University of Hong Kong, Hong Kong

This study examined the role of oral language proficiency and phonological awareness in Chinese and English word reading acquisition for Chinese ESL young children. Hong Kong preschool-age children (N = 97) were administered with measures of word reading, phonological awareness and oral language proficiency in both Chinese and English. The results indicated that, with age and general intelligence statistically controlled, both English expressive vocabulary and English phoneme awareness were significant predictors of English reading. Chinese tone awareness made significant contribution in predicting Chinese word reading but Chinese rhyme awareness and Chinese oral language tasks were insignificant predictors. In addition, English phonological awareness at syllable and rhyme levels significantly predicted Chinese word reading and Chinese phonological awareness (tone awareness) significantly predicted English reading after controlling for age and general intelligence. The findings demonstrate the unique and significant role of phonological awareness across languages among ESL children learning two very different writing systems and suggest that phonological awareness might be a shared competence across languages. Educational implications of the present study will be discussed.

Aims

The aim of this study is to explore the contribution of phonological awareness and oral language proficiency to Chinese and English reading development among Hong Kong Chinese ESL learners. We focused on two research questions. First, to what extent are second language (L2) phonological awareness skills and L2 oral language skills associated with English reading among young Chinese ESL children? Second, to what extent do Chinese and English phonological awareness skills predict Chinese and English reading in young ESL children? It is of our interest to examine the role of phonological awareness because it is largely overlooked in the current instructional approach of English reading for Hong Kong Chinese ESL learners. A better understanding on its role in early L2 reading development is necessary for researchers and educators to develop curricula and teaching strategies which may have long terms impacts on academic success for young ESL learners.

Method

In this study, English and Chinese phonological awareness tasks, oral language measures and English and Chinese reading were administered to 97 beginning readers in Hong Kong from four kindergartens with Cantonese as a medium of instruction. A measure of general intelligence was also administered as a control variable. The measures employed are summarized in Table 1 (See Appendix 1).

Results

Table 2 (See Appendix) presents the partial correlations among the measures after controlling for age and general intelligence. Results indicated that English word reading was significantly correlated with various oral language proficiency measures. It was also significantly associated with English phonological awareness measures at different levels. Chinese reading was significantly associated with Cantonese tone awareness but not with Chinese rhyme awareness. For the associations across L1 and L2, English word reading was significantly correlated with Chinese oral cloze and Cantonese tone discrimination whereas Chinese word reading was significantly associated with English phonological awareness at different levels.

Hierarchical multiple regressions were performed to examine the contribution of L1 and L2 phonological awareness and oral language proficiency to Chinese and English reading. We entered age and general intelligence in Step 1 to control for its effects on word reading. Then, we entered oral language proficiency measures in Step 2 because we are interested to explore to what extent English and Chinese word reading would be predicted by phonological awareness skills, which are the missing elements in the current English language curriculum in Hong Kong preschools, after controlling for proficiency level. As shown in Table 3 (See Appendix), picture naming, the measure of expressive vocabulary (picture naming) and phoneme awareness (phoneme identification) were two significant predictors of English reading. Both English oral language proficiency and English phonological awareness accounted for unique additional variance of English reading. For Chinese reading, oral language skills were not significant predictor of Chinese reading and only the Cantonese tone discrimination significantly predicted Chinese reading.

To examine the cross language associations, hierarchical regressions were conducted to predict English reading from Chinese phonological awareness and Chinese reading from English phonological awareness. As shown in Table 4 (See Appendix), Chinese tone discrimination was a significant predictor of English reading whereas English syllable deletion and rhyme detection significantly predicted Chinese reading but not phoneme identification. Cross-language transfer of phonological awareness skills was demonstrated.

Theoretical and educational significance

This study has provided initial evidence of the important role of L2 phonological awareness, particularly phoneme awareness, and oral language proficiency in early English reading development among Chinese ESL learners. The findings also show that phonological awareness skills transfer across languages which support the notion that phonological awareness is a shared competence across languages. Given that very little phonological instruction is provided in Hong Kong kindergarten, current study points to the need to further investigate the role of phonological awareness instruction in promoting English reading development for Chinese ESL young children.

PAPER PRESENTATION

Depth of Processing in Reading Comprehension

John Kirby, Queen's University, Canada; Bozena White J, Queens University, Canada

We investigated the role of depth of processing in the reading comprehension of 141 Canadian high school students. Items on three reading comprehension tests were classified into three levels of comprehension, Details, Main ideas, and Themes. Regression analyses indicated that the deep approach to learning was only predictive of the deepest, thematic level of comprehension. Further analyses identified students whose reading comprehension was lower than would be expected from their general and word reading abilities; these students performed worse than others at each level of comprehension, and continued to do so after controlling vocabulary, working memory, and the deep approach to learning. These results indicate that the depth of processing framework can be applied to reading comprehension and suggest a number of potential benefits. Students with low reading comprehension performance may benefit from help in basic skills or from instruction that orients them towards deeper levels of processing.

Aims

The purpose of this paper is to examine the role of depth of processing in high school students' reading comprehension. Current theories of reading comprehension (e.g., Kintsch, 1998) describe three levels of representation, which correspond to progressive levels of depth: a surface representation, a textbase representation (in which main ideas and details are distinguished), and a situation model in which text information is combined with prior knowledge to provide a dynamic and thematic representation of the events or material conveyed by the text. Kirby and Pedwell (1991) offered an alternative description, referring to the detail, main idea, and thematic levels of comprehension. However, measures of reading comprehension that are commonly used in schools do not assess these levels separately. Our first aim in this study therefore is to examine whether these levels can be reliably distinguished in commonly used tests.

Depth of processing in learning can be assessed by self-report measures of approaches to learning (e.g., Biggs, 1987; Entwistle, 1989). Although the deep as opposed to the surface approach to learning would appear to be desirable for better reading comprehension, there is a lack of evidence on this point. Approaches to learning may be constrained by lower-level skills (e.g., word recognition), and the deep approach may only be valuable for the deeper forms of comprehension (i.e., main ideas and situation model). Our second aim therefore is to examine the effects of approaches to learning on reading comprehension, after controlling basic skills.

Our third aim is to identify a group of unexpected poor comprehenders (students whose comprehension scores are much lower than would be expected from their intellectual and word reading abilities; e.g., Cain & Oakhill, 2006). We intend to determine whether their comprehension difficulties are confined to specific levels of comprehension or are apparent at all levels.

Method

The participants were 141 English-first-language Grade 10 students in a rural Ontario high school (mean age 15 years 4 months, SD 7.5 months; 80 girls and 61 boys), from a range of socio-economic backgrounds.

Three measures of reading comprehension were administered: (a) Test-R (Reading) of the Canadian Tests of Basic Skills (CTBS, Nelson, 1998), in which students answer multiple-choice questions after reading short passages; (b) the Ontario Secondary School Literacy Test (OSSLT), a government-mandated curriculum-based test, in which students read various forms of text and responded to multiple-choice and open-response questions; and (c) a Summary Writing task in which students read a 680-word text and later wrote a text-absent summary (similar to the task used by Kirby & Pedwell, 1991); this task yields scores at the relevant detail, main idea, and thematic levels.

Students' approaches to learning were assessed with the Revised Two-Factor Study Process Questionnaire (R-SPQ-2F, Biggs, Kember & Leung, 2001), a self-report questionnaire consisting of 20 five-point Likert-type scale items. Deep and surface approaches are measured.

Measures of general nonverbal ability, vocabulary, working memory, and word reading accuracy were also administered.

Findings

Items from the three reading comprehension measures were classified separately by two coders into the three levels of details, main ideas, and themes. Classification was moderately consistent and differences resolved in discussion. (We will provide illustrative examples of items and their classification.) Based on these classifications, we formed three reading comprehension z-score variables: Details, Main ideas, and Themes.

To address our second aim, we carried out hierarchical regression analyses in which the Detail, Main idea, and Theme variables were the outcomes. We entered nonverbal ability, vocabulary, working memory, and word reading ability in the first step, and then deep and surface approaches to learning in the second step. Results indicated that the surface approach was not related to any level of comprehension, and that the deep approach was significantly related only to the Theme level of comprehension, $\beta = .228, p < .05$.

To address our third aim, we used White and Kirby's (2008) regression technique for identifying unexpected poor comprehenders (those whose reading comprehension is lower than expected, $N = 37$), expected average comprehenders (those whose comprehension is as predicted, $N = 34$), and unexpected good comprehenders (those whose comprehension was greater than predicted, $N = 21$). Analyses of variance and covariance (in which vocabulary, working memory, and the deep approach were controlled separately) demonstrated that the three groups were significantly different at each of the three levels of reading comprehension. Group profiles will be shown to illustrate these results.

Theoretical and Educational Significance

These results indicate that the depth of processing framework can be applied to measures of reading comprehension. The results should provide more detailed feedback to students and teachers about students' strengths and weaknesses, and should provide a stronger basis for intervention. We recommend that commercial test providers make greater effort to assess the different levels separately.

The finding that the deep approach to learning is associated with thematic comprehension suggests that interventions should address students' conceptions of learning. Further studies of this relationship are suggested, investigating, for instance, whether changes in tasks instructions produce deeper thematic comprehension.

The present results show that the problems of poor comprehenders are pervasive, across all levels of reading comprehension. Previous studies (e.g., Cain & Oakhill, 2006) have indicated that these students have weak semantic and inferential skills; our interpretation of the present results is that these semantic and inferential difficulties occur as the lowest levels of cognitive representation are being established and then spread to prevent the higher levels from being established. We recommend that intervention studies be designed to either address the basic semantic/inferential difficulties, or to circumvent those difficulties by focusing on deeper learning strategies (see Lawson & Kirby, in press).

PAPER PRESENTATION

Enhancing Teacher Education: The Case Method of Teaching to Promote Cross-Linked Thinking

Ralf Merkel, Humboldt Universität zu Berlin, Germany; Annette Upmeyer zu Belzen, Humboldt Universität zu Berlin, Germany

Student teachers experience difficulty in recognising problems of teaching in complex (teaching) situations (Well 1999). This paper presents an intervention study to foster cross-linked thinking in masters students to address this shortcoming. The module "subject specific teaching", which prepares students especially for teaching, will be targeted to include material on the case method of teaching (Shulman 1992, 1996, Levin 1995).

The model of cognitive complexity by Schroder et al. (1975) serves as the theoretical background of this study. It distinguishes three components: discrimination, differentiation and integration, which represent different aspects of cross-linked thinking.

The cases consist of teaching situations, specifically designed and generated for the targeted module in order to promote the students' capability to think in a cross-linked way. The focus of the cases will be on problems dealing with pedagogical content knowledge in the field of biology didactics.

The intervention's effectiveness will be measured by using a two-group pre/post-test design. The intervention and the test will be carried out between October 2010 and April 2011. The main focus will lie on the comparison of the intervention and the control groups' ability in cross-linked thinking. The measurement of the students' ability in cross-linked thinking will be evaluated on the basis of qualitative text analysis. The results are expected to be available in April 2011.

German teacher education is divided into three parts: specialised branches of science, general educational knowledge and specialised subject didactics. This reflects the division of professional teacher knowledge (based on Shulman 1987) into content knowledge (CK), pedagogical knowledge (PK) and pedagogical content knowledge (PCK) (Baumert & Kunter 2006, Park & Oliver 2008). In this context PCK can be seen as the link between CK and PK (Terhart 2000). The structure of teacher education in Germany can be one explanation for the students' fragmented knowledge (Terhart 2000). This is evident in the lack of student teachers' ability to comprehend complex problem situations and their reactions in such situations (Well 1999). To implement their knowledge, students have to bring together the separate parts of their professional teaching knowledge, necessitating an integration of theoretical parts in order to apply them in practice. This can be achieved by developing cross-linked thinking in the masters of education. Within this framework of integration and cross-linked thinking, the central aim is to develop students' cross-linked thinking abilities in the masters seminars of biology didactics.

The model of cognitive complexity (Schroder et al. 1975, Müller 1999), which distinguishes three components: differentiation, discrimination and integration, serves as the theoretical background of this study. The model represents different aspects of cross-linked thinking. Differentiation is the capability to split information found in a (teaching) situation into different dimensions. Dimensions are main categories, which can be identified in complex (teaching) situations. Therefore differentiation is a measurement of the quantity of main categories, which can be identified in a (teaching) situation. Discrimination is the capability to grade within one dimension (Müller 1999). The third component of the model is integration, which includes the capability to evaluate situations, to find alternatives, to compare and contrast solutions and advantages and disadvantages of the found solutions. An additional theoretical component employed in this study is the Angebots-Nutzungs-Modell (Helmke 2009), which describes a lesson's influencing factors. The model is adapted to be applicable to a university setting and is reduced to focus on the following components: Angebot (supply), Nutzung (use) and Ertrag (output).

For this study the seven categories of PCK specifically created for biology by Schmelzing et al. (2008) are modified and arranged into ten categories of PCK in the field of biology didactics.

To foster the ability to deal with complex and unforeseen problems in complex teaching situations, studies into the effectiveness of implementing the case method approach during teaching were conducted in the US teacher education program (Shulman 1992, Levin 1995). A teaching event is defined as a case (Shulman 1992). A case consists of theoretical and practical components and as such can be considered a piece of controllable reality. Therefore cases are particularly suited to be employed in teacher education programs.

The following research questions are posed, based on the described problems, the theoretical components of cross-linked thinking and the ten categories of PCK in the field of biology didactics.

To what extent can the case method of teaching in conjunction with the theoretical categories of PCK help to develop the cross-linked thinking model with its components of discrimination, differentiation and integration?

How can the developmental processes of the students, over several seminars, to analyse different cases in the context of cross-linked thinking be described qualitatively?

The case method of teaching will be implemented in the module: "subject specific teaching", which prepares students especially for teaching, in order to develop biology education students' cross-linked thinking. This module is divided into three parts: the preparatory seminar, the in-school practical component (four weeks) and the post processing consolidation seminar. In all three parts, cases specifically designed for the module will be implemented. They are designed and generated on the basis of the ten different categories of PCK, interviews with student and expert teachers and written cases from biology education students' practical experience during the summer semester of 2010.

The cases are divided into three acts (Shulman 1992). At first the content information is described (goals, the expected unfolding of the lesson and basic parameters). In the second act, the account of what actually happened is presented, including unanticipated problems and difficulties. Both acts are analysed by the students during their seminar and the problems are categorised into different aspects of PCK. In act three the students have to interlink the identified aspects of PCK. The aim of this act is to reflect on the case and find alternative possibilities to deal with the identified and classified problems.

The effect of the intervention will be evaluated by using a two-group pre/post-test design. A pilot study was carried out in the summer semester of 2010, to test the implementation of the case method and measuring instruments. The main study will be carried out in the winter semester of 2010/2011. To determine the students' ability in cross-linked thinking, the participants will analyse a case in the pre- and post-tests. The categories of PCK in the field of biology didactics in combination with the components of cross-linked thinking provide the basis for analysis; this is combined with Mayring's (2003) qualitative content analysis method. To ascertain information about the students' development process in their ability to think in a cross-linked manner, a learning diary will be kept, based on Helmke's Angebots-Nutzungs-Modell (2009).

The measurement of the pre- and post-tests as well as the learning diaries will be carried out on the basis of PCK in connection with the cross-linked thinking model and Mayring's qualitative text analyses (Mayring 2003).

The participants of the seminars are all master students in their first or third semester. All of them have successfully completed a Bachelor of Science or Bachelor of Arts. Therefore it is assumed that the students have detailed content knowledge of biology and a basic pedagogical and pedagogical content knowledge.

The results of the pilot study are currently being evaluated. The first results of the main study are expected to be available towards the end of April 2011.

PAPER PRESENTATION

Self-regulated learning of students' motivation by preservice teachers

Sylvie Frechette, Université du Québec à Trois-Rivières, Canada; Frederic Legault, Université du Québec à Montréal, Canada; Monique Brodeur, Université du Québec à Montréal, Canada

The study investigates self-regulatory processes used by preservice teachers to learn to motivate their students within the practicum. Data was collected from 79 trainees who posted a message describing a motivation problem in electronic discussion forums. Also, 15 trainees were prompted to describe in recall interviews a classroom situation where they learned to motivate their students. Twelve self-regulatory processes were found in interviews, and nine in forums. A description and frequencies of the processes will be presented. Some processes considered as crucial will be presented in details. Positive correlations were found among phases of self-regulation, and between the number of

different self-regulatory processes used by trainees within forums and the number of motivational strategies they proposed. Trainees who used more self-regulatory processes generated more motivational strategies.

Introduction

Given the growing body of evidence reflecting the benefits of developing self-regulatory skills on academic performances, concerns have been expressed regarding the development of self-regulatory processes preservice teachers (Kremer-Hayon & Tillema, 1999). This suggests that teacher education programs should focus more on the development of self-regulation to give preservice teachers greater control over their theoretical and practical knowledge acquisition within the context of life-long professional development. However, to our knowledge, no study has reviewed the self-regulatory processes used by preservice teachers within their practicum to learn a complex professional task such as motivating students.

Objectives

The objectives of the study are: 1) to identify and describe the self-regulatory processes used by preservice teachers to learn to motivate their students within the practicum and 2) to examine the relation between the trainees' use of self-regulatory processes and their capacity to propose motivational strategies.

Theoretical Framework

According to social cognitive theory, self-regulation is a process whereby students activate and sustain cognition, behavior and affects that are involved in the successful completion of learning tasks. Self-regulation consists of three successive and cyclical phases: forethought, performance and self-reflection. The forethought phase sets the stage for the efforts; it consists of goal setting, strategic planning, self-efficacy beliefs, goal orientation and intrinsic interest. The performance phase occurs during the efforts and acts on attention; it consists of attention focusing, self-instruction or imagery and self-monitoring. The self-reflection phase follows the efforts, affects, and the learner's response to efforts; it consists of self-evaluation, attributions, self-responses and adaptivity (Zimmerman, 1998). Preservice teachers and teachers can play a crucial role in their students' motivation (Pintrich & Schunk, 2002). They can affect motivation in many ways through the implementation of numerous strategies in class.

Methodology

a) Participants and procedure

The study took place within a classroom management course delivered to 129 students in the third year of a secondary education degree program of a well known university. This course was given concurrently with a five-week practicum; 115 students were completing the practicum. All trainees were given access to four different forums. They had to post messages of at least 200 words in a specific forum according to the subject addressed. Only the forums on students' motivation were used for this study, and 79 trainees posted a message describing a motivational problem. Additionally, in a one-hour recall interview, 15 trainees were prompted to freely describe a classroom situation where they learned to motivate their students.

b) Data source

The forum and interview transcripts were coded according to Zimmerman's model (1998). One procedure was used to score the interviews, and three for the forums. First, a frequency score was created by counting the number of times that a self-regulatory process appeared in the forum and interview transcripts. Second, a dichotomous score that describes whether a trainee used a process was also considered for the forums. Third, the motivational strategies appearing in forums were also counted. Using Miles & Huberman's formula (1984), a reliability index of 84% was obtained for the self-regulatory processes appearing in the interviews, 89% for the self-regulatory processes in the forums, and 91% for the motivational strategies generated by the forums.

Results and Discussion

Twelve self-regulatory processes were found in interviews. In general, trainees set both distal outcome and proximal process goals. Their self-efficacy beliefs were increased among other things by good planning for teaching. Trainees found interest in their relations with students. They mainly chose strategies in order to reach process goals. They monitored the use of these strategies by observing student behaviour in class. They reflected upon their actions: they evaluated it positively or negatively, made causal attributions and adapted their subsequent performance in the practicum. Some were satisfied, while others were unsatisfied or frustrated. A mastery learning goal orientation was reported by only one trainee. A detailed description of the more important process according to literature will be presented.

Nine processes were present in the forums. The processes most frequently reported were goal setting (46.9%), strategic planning (77.2%) and monitoring (98.9%). The other process frequencies include: 29.2% for adaptive

inferences, 27.9% for both self-evaluation and causal attributions, 11.4 % for self-reactions, 12.1% for self-efficacy beliefs and, finally, 8.9% for interest. Goal orientation, attention focusing and self-instructions processes were absent. Pearson's correlation coefficient was used to examine the relationship among the three self-regulation phases. Significant correlations were found between phases 1 and 2 ($r = 0.541$, $p = 0.001$) and between phases 2 and 3 ($r = 0.369$, $p = 0.001$).

178 motivational strategies ($M: 2.25$, $SD: 2.03$) were collected through the forums. Pearson's coefficient was used again to evaluate the correlation between the forum dichotomous scores and the motivational strategy numbers generated by the forums. A positive correlation was found ($r = 0.298$, $p = 0.005$).

Conclusion and Educational Significance of the Study

This study identifies the self-regulatory processes used by trainees to learn to motivate their students. Trainees used all self-regulatory processes at different levels in learning about students' motivation. Monitoring, which is considered by many authors as a vital one, is the most frequently used. Trainees who used more self-regulatory processes generated more motivational strategies. The description of self-regulatory processes used to learn to motivate students could help educators to support preservice teachers correctly in their learning.

PAPER PRESENTATION

Knowledge for teaching mathematics at the beginning and end of teacher education (TEDS-M option)

Erich Ramseier, PHBern – University of Teacher Education, Switzerland; Fritz Oser, Universität Freiburg, Switzerland; Horst Biedermann, University of Fribourg, Liechtenstein; Margit Kopp, University of Teacher Education Luzern, Switzerland; Sibylle Steinmann, PHZ Luzern, Switzerland; Christian Bruehwiler, University of Teacher Education St. Gallen, Switzerland; Samuel Krattenmacher, University of Teacher Education St. Gallen, Switzerland

The Teacher Education and Development Study in Mathematics (TEDS-M) undertakes an international comparison of mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK) of future primary and lower secondary school teachers at the end of their teacher education. For an estimation of the quality of teacher education, it is necessary to determine the level of knowledge also at the beginning of teacher education, since this is a prerequisite for the separation of treatment and selection effects. Therefore, in a Swiss TEDS-M option, students were tested at the beginning of their teacher education ($N = 1405$). This paper examines the methodological prerequisites of the comparison of the two cohorts and presents its main result. For future primary teachers, application of the Rasch model shows that measurement invariance between the beginning and the end of teacher education is assured. Furthermore, MPCK and MCK can be distinguished empirically ($r_{\text{latent}} = .80$). The international TEDS-scale may be used since the international ability estimates of students at the end of teacher education can exactly be reproduced locally and these scores correlate highly with nationally established scores ($r \geq .98$). The MPCK mean is significantly higher at the end than at the beginning of teacher education, yet this is not true for MCK. This distinction is plausible since the focus in primary teacher education is on imparting teaching. The results allow for detailed Swiss analyses. They also show the difficulty to interpret international TEDS-M data which include measurement only at the end of teacher education.

Aims

Knowledge for teaching mathematics is essential for high-quality instruction and student progress at school (Baumert et al., 2010). It is therefore important to know what knowledge future primary and lower secondary school teachers have acquired at the end of their teacher education. The Teacher Education and Development Study in Mathematics (TEDS-M) internationally compares this knowledge (Tattoe et al., 2008; see also Blömeke, Kaiser, & Lehmann, 2010; Oser et al., 2010). Thereby mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK) are distinguished and separately measured. The "overall goal of this study is to find better ways to help teachers learn what they need to know to teach mathematics well" (Tattoe et al., 2008, p. 8). For an estimation of the quality of teacher education and for proposing ways of improvement, it is not sufficient to know the characteristics of teacher education programs and the level of teaching knowledge attained at their end. Determining the knowledge

level at the beginning of teacher education is another prerequisite for the separation of treatment and selection effects. Therefore, in a Swiss TEDS-M option, students were tested at the beginning of their teacher education. This paper examines the methodological prerequisites of the comparison of the two cohorts and presents its main result. Research questions are: Is measurement invariance assured between the beginning and the end of teacher education? May the metrics of the international TEDS-M scales be used? Are MCK and MPCK separable dimensions? What is the mean level of MPCK and MCK at the beginning and at the end of teacher education in Switzerland (German speaking part)? Procedure TEDS-M developed different tests for future primary and lower secondary mathematics teachers. The Swiss project conducted a census in the German part of Switzerland using these tests. At the end of teacher education, 936 (76%) of all future primary teachers and 141 (81%) of all future lower secondary teachers participated. In parallel, 1226 future primary and 179 future lower secondary teachers were tested in their first term of teacher education applying the same test design.

Analysis and results

Preliminary results concentrate on future primary teachers. Swiss data were scaled based on the Rasch model and using Conquest (Wu, Adams, Wilson & Haldane, 2007). Since analyses for MCK and MPCK showed a good model fit (infit for all items between .92 and 1.07) and no differential item functioning between the beginning and at the end of teacher education, measurement invariance is granted. Swiss raw data of students in their final year were locally prepared and scaled based on information about the international procedure. This led to the same person ability estimates as in the international TEDS-M data base. Therefore, the procedure can reliably be applied to students in their first year of teacher education to produce internationally comparable estimates. Yet the nationally and internationally determined relative item difficulties show considerable differential item functioning for many items (see figure 1 for MCK items). The international item difficulties are therefore not best suited for describing the knowledge structure in Switzerland. Since there is a high correlation between person scores that are estimated using international item difficulties and those using national item difficulties, scores based on the international scale may nevertheless be used to analyse test results. As theoretically expected, the latent correlation between MCK and MPCK is high ($r = .80$, two-dimensional scaling model). Yet it demonstrates that these constructs are empirically distinguishable. The MCK mean at the end of teacher education ($M = 543$, international scale) is not significantly higher than at the beginning ($M = 539$, t-Test). Yet students at the end of teacher education score significantly higher on MPCK ($M = 537$, effect size $d = 0.17$, $p = .0001$) than at the beginning ($M = 527$). The final paper will show whether results are different for future lower secondary mathematics teachers.

Significance of the research

Although longitudinal data are absent, the analysis suggests that the mathematical content knowledge of future primary teachers is not appreciably growing during teacher education. The high Swiss results in the international TEDS-M comparison therefore do no proof that Swiss teacher education is of high quality in this respect. A high level of mathematics knowledge acquired in earlier stages of education is probably a better explanation. This uncertainty of the interpretation of results of TEDS-M might hold for other countries. There is more evidence for growth in mathematics pedagogical content knowledge. This is plausible since the focus in primary teacher education is on imparting teaching skills rather than mathematical knowledge. The research establishes the basis for analyzing in a next step whether differences between groups of students, in particular students enrolled in different teacher training institutions, are rather a consequence of differing selection or treatment within teacher education.

PAPER PRESENTATION

Teachers' Professional Competences and Active Learning

The aim is to present how teachers' professional competences and active learning are related in Finnish teacher education. The theoretical framework is based on a concept that consists of a broad view of teachers' professional role in schools and society. The framework of active learning is based on theories that consider learning as constructivist and collaborative processes. Methods of the study are quantitative and qualitative. Student teachers in two universities (n=454) participated in the research. The quantitative data is analysed using descriptive statistics and using also ANOVA, correlate and multivariate methods and Factor Analysis (Principal axis method with Varimax and Promax rotations). The qualitative data are analysed using a content analysis techniques. The strongest relationships exist between active learning and the professional competences in the tasks that require a strong reflective orientation and commitment in teaching profession: Revising students' learning environments, Working as a change agent in a society, promoting Self regulated learning, Critical reflection of own work, and Critical assessment of teacher education. In open ended answers six main categories could be found: Collaborative working culture, Teaching practice with opportunities to experiments, Opportunities to make own to design or develop large units for own or pupil's learning, Research studies including writing BA and MA thesis. The large course units programs focusing on understanding phenomena in life and connections between different disciplines in a new and deeper way. Subject matter projects or subject matter pedagogy requiring independent inquiring or collaborative knowledge creation.

Objectives

The aim is to present how teachers' professional competences and active learning are related in Finnish teacher education.

Perspectives and theoretical framework

The theoretical framework is based on a concept that consists of a broad view of teachers' professional role in schools and society. It considers a teacher as a researcher and a reflective practitioner, and sees teacher education as an inquiry-oriented process (e.g. Darling-Hammond, 2010; Carr & Hatrnett, 1996; Hargreaves, A, 1994; Hargreaves, D, 2000; Smyth, 1995; Oser 1994; Tabachnick & Ziechner 1991; Schön 1991.)

The framework of active learning is based on theories that consider learning as constructivist and collaborative processes. Active learning consists of independent inquiry, structuring and restructuring of knowledge, a problem-solving orientation, a critical approach and an evaluation of knowledge. Learners can elaborate on applications of knowledge and s/he may also produce new knowledge individually and collaboratively (e.g. Scardamalia 2002; Sfard 1998; Nonaka & Toyama, 2003). Active learners develop inquiring their skills and to learn to reflect on, and control their own learning processes (e.g. Pintrich & McKeachie, 2003). Knowledge is not an individual possession, but socially shared and emerges from participation in sociocultural activities.

Methods and modes of inquiry

Methods of the study are quantitative and qualitative. Student teachers in two universities participated in the research. They assessed in the web-base survey how teacher education had provided them with professional competences needed in a high standard profession (40 questions with a scale 1-5). They also assessed what kinds of experiences on active learning they have had and how often these methods were used (20 questions with a scale 1-5). There were also open/ended questions about strengths and weaknesses of their TE from the view point of active learning. The quantitative data is analysed using descriptive statistics and using also ANOVA. In addition correlate and multivariate methods are applied. Data reduction methods such Factor Analysis were used (Principal axis method with Varimax and Promax rotations) in the analysis of the Active Learning questionnaire. The qualitative data has been analysed using a content analysis techniques.

Data sources

The data was collected by among students of class teacher and subject teacher education programs at the Universities of Helsinki and Oulu. The departmental mailing lists were used in the data gathering. The Students could assess their TE programs anonymously.

In web based surveys 605 students visited on Web sites, but the number of students who responded to all questions varies around 30-42% from the total number of student teachers. The total number of students in this study is 454.

Results

Professional competences

The highest professional competences have been achieved in the following skills: (1) Designing of instruction, (2) Critical reflection of own work, (3) Becoming aware of ethical basis of teaching profession, (4) Life long professional growth, (5) Self-evaluating of own teaching, (6) Using teaching methods, and (7) Development of own educational philosophy. They all have the Mean value at least 3.5 and standard deviation is less than 1.00. These all are high level professional skills and necessary for experts who develop their own work. The weakest skills student teachers have achieved for administrative tasks and management of tasks outside a classroom (keep on eye on students during recess, school festivals, trips, morning assemblies etc.). Also co-operation with parents, representatives of work life and cultural partners are weak as well as working in cooperative action research projects, student welfare groups and in other school community groups.

Active learning

The students assessed what kinds of active learning experience they have the most often. They worked intensively with their assignments, applied knowledge, and tried to understand matters and phenomena even though it would take time). They were tutored, if needed, but otherwise they worked independently or in peer groups. They discussed together about the best solution for the assignments and self-evaluated their own products. They also sought much additional knowledge. These experiences they had almost every week.

Relationships between professional competences and active learning

The strongest relationships exist between active learning and the professional competences in the tasks that require a strong reflective orientation and commitment in teaching profession. Active learning has the strongest correlations (.37 -.40) with the variables Revising students' learning environments, Working as a change agent in a society, promoting Self regulated learning, Critical reflection of own work, and Critical assessment of teacher education.

Students' responses to open ended questions

Writings of 253 students were analysed using content analysis techniques. Five main categories could be found. These are not separate but integrated with each others.

Collaborative working culture, active discussions with peers and professor/supervisors, knowledge sharing in coursework, examinations where a group is responsible for outcomes.

Teaching practice with opportunities to experiment, to work with pupils in schools and collaboration with student teachers, supervisors and teachers who are responsible for theoretical studies of pedagogy.

Opportunity to own applications, freedom to make own plans, design or develop large units for own or pupil's learning.

Research studies including writing BA and MA thesis, commitment to inquiry, learning critical approach to knowledge. The large course units programs that have been implemented through out with active learning methods focusing on understanding phenomena in life and connections between different disciplines in a new and deeper way. Subject matter projects or subject matter pedagogy requiring independent inquiring or collaborative knowledge creation.

Scientific and scholarly significance of the study

The study gives evidence that there is the relationship between active learning and high level professional competences. The best active learning experiences emerge in collaborative working and study culture, in teaching practice and research studies. Students appreciate to have freedom to experiment and design their own applications. If we want to have teachers as high professionals, also learning methods used in teacher education must be in line with this purpose. If we want to change schools towards more active learning in our global world, also teacher education should promote these methods. This study opens important scenarios for the development of teacher education.

PAPER PRESENTATION

Barriers and drivers of participants' satisfaction in CSCL environments Using the Kano model

Helga Dorner, Central European University, Hungary

This study examines Hungarian in- and pre-service teacher participants' satisfaction with the online mentoring experience in CSCL environments ($N_{in} = 43$; $N_{pre} = 116$). In the participant satisfaction analyses, the Kano model was employed, which contributed to identifying the relative priority of improving components of the online processes. We found that online communication is a one-dimensional attribute, which leads to linear increase of participant satisfaction. Results also showed that participants' skills and competences involved in general computer usage and their Internet abilities were must-be attributes. We thus concluded that online communication and effective

facilitation are inevitable constituents of the online mentoring process, and they lead to higher participant satisfaction and feeling of success. Additionally, successful learning experience is also dependent on participants' skills and competencies concerning general computer usage and their Internet abilities.

In their model of CSCL theory and research for instructional design, Brandon and Hollingshead (1999) identified participants' satisfaction with computer-supported collaborative learning (CSCL) as one of the crucial factors when evaluating teaching and learning processes. While early studies in the field focused on the comparison of online and face-to-face learning experience, researchers' attention later on turned to identifying factors that contribute to or decrease participants' satisfaction. Exploring satisfaction with the online learning experience included the study of interaction and the facilitator's role in enhancing online learner satisfaction (Arbaugh, 2001; Bolliger, 2004); investigation of positive relations between participant satisfaction, social interaction and collaborative learning (Gunawardena & Zittle, 1997; Richardson & Swan, 2003); and also the identification of factors that contribute to students' dissatisfaction (So and Brush, 2008). In general, studies in the field conclude that the extent to which participants are satisfied with online courses contributes to improving online learning achievement thus measuring satisfaction with online learning should be part of the instructional design. The Kano model to survey satisfaction The Kano model of consumer satisfaction is a research tool to identify and classify the product criteria and attributes that create more satisfaction than others (Kano, Hinterhuber, Baison, & Sauerwein, 1984). The model classifies product attributes into four categories (Xu, Jiao, Yang, & Helander, 2009): (1) must-be or basic quality attributes; (2) one-dimensional or performance attributes; (3) attractive or excitement attributes; and (4) indifferent attributes. The lack of must-be attributes leads to extreme dissatisfaction. One-dimensional attributes entail those for which better fulfilment leads to linear increase of satisfaction. Attractive attributes are in general unexpected by the customers, their presence can lead to satisfaction. Indifferent attributes are those that the customer is not especially interested in.

Aims of the research

The reason for measuring participant satisfaction with our online in- and pre-service teacher training scenarios was twofold. First, our aim was to identify factors that increase or hamper participants' satisfaction with the online learning experience i.e. drivers and barriers of satisfaction. We assumed that effective facilitation and online communication lead to higher participant satisfaction and feeling of success. Second, we intended to find and test a method that helps us deciding the relative priority of improving components of the teaching and learning process in a CSCL environment. According to our current knowledge, the Kano model has only been applied in consumer satisfaction studies thus, we also wanted to address the question whether it is applicable in education research contexts at all. Research methodology Hungarian in- and pre-service teacher communities ($n_{in} = 43$; $n_{pre} = 116$) were involved in the study. In both communities, the Mentored Innovation Model (Author, 2008) was utilised as the instructional context for the professional training exercise. This meant subject-specific online collaborations in small-groups, mentored and scaffolded by online facilitators who were experienced in delivering teacher professional trainings.

We used two research tools: (1) participant satisfaction survey and (2) ICT metrics (Török, 2007). Both tools relied on quantitative data and intended to collect self-perceived values. The former one is a Likert-type survey instrument (consisting of 25 items) for investigating and developing a model of participant satisfaction. The items used a 4-point response scale and focused on: (1) participants' global satisfaction, (2) satisfaction with the facilitator's activity, (3) online communication in the CSCL environments, and (4) the participants' perceived social presence. The latter tool aims at describing the (individual) participants' ICT-competence, which we divided into two groups of indicators: those focusing on (1) skills and competences involved in the general computer usage and (2) Internet abilities.

Results and Discussion

We identified online communication in the CSCL environment as a one-dimensional attribute ($p = .002$ and $p = .000$), which leads to linear increase of participant satisfaction. Accordingly, the higher is the value of participants' satisfaction with the online interactions scaffolded by the facilitators, the higher participant satisfaction grows.

Results concerning the participants' skills and competencies involved in the general computer usage ($p = .003$) and their Internet abilities ($p = .022$) were identified as must-be attributes. Thus, we claim that if participants lack these skills, it would lead to extreme dissatisfaction. Hence, our assumption that effective facilitation and online communication contribute to higher participant satisfaction and feeling of success was supported. Additionally, we found that successful participation is also dependent on the participants' competences in general computer usage and their Internet abilities. We also intend to discuss the limitations of the applied research tools and suggest further research methodologies applicable.

PAPER PRESENTATION

Being a teacher? No thanks. Motives for novice teachers not being willing to teach (anymore)

Katrien Struyven, University of Brussels (VUB), Belgium

Teacher shortages are partly explained by novice teachers who do not start or continue to teach: Who are they? And why are they not motivated to teach (anymore)? A survey investigation was conducted among 235 Flemish 'exited' teachers (from 2309 graduates). Exit attrition applies to 16%, however, more to males and Secondary school teachers. Interestingly, 1/3 of the exited teachers, never practiced teaching after graduation. Five sets of reasons explain exited teachers' rationale: 1) job satisfaction and relations with students, 2) school management and support, 3) workload, 4) future prospects and 5) relations with parents. Interestingly, the lack of future prospects and support by colleagues and management in the school are two 'lived experiences' that distinguish between teachers who never entered teaching practice and those who have had teaching experience after graduation. Implications are discussed.

Introduction

In many countries (e.g. UK, Belgium, the Netherlands, US), teacher shortages are eminent. Hence, it is important to attract students into teacher education and to encourage them to engage in a professional and enduring career in teaching. The fact, however, is that many student teachers never start teaching or leave education within the first five years following graduation; the problem of exit 'attrition' (i.e. teachers who change careers) (Ingersoll, 2001; Hahs-Vaughn & Scherff, 2008). The purpose of the present study is twofold. On the one hand, the study sets out to find out who these teachers are. On the other hand, it aims to understand why qualified, novice teachers in Flanders (Belgium) do not start teaching, or give up teaching within five years of graduation.

Method

A survey study was conducted. 370 teachers (of a sample of 2309 teacher education graduates) were not teaching (anymore), five years after graduation; that is 16.02%. These teachers were asked to fill out the questionnaire and return it, which 235 respondents successfully did (RR= 63.51%). Instrument A questionnaire was designed on the basis of the review of the international research literature on (exit) attrition. The main part of the questionnaire described 66 reasons that may have been decisive for not teaching (anymore). For each reason, respondents had to indicate on a 5 point-scale whether the reason had no effect (N.A.); whether it played a small part (+), a considerable part (++), a large role (+++), or a very significant role (++++ in their decision not to teach (anymore). Results show that male teachers (25.49%) tend to leave the teaching profession more readily than female colleagues (13.37%). Exit teachers are, in particular, secondary school teachers (24.27%), followed by elementary school novice teachers (11.42%) and graduates in kindergarten education (9.73%). For secondary education teachers, attrition rates are highest in following subject specialties: Physical training/Sports (31.9%), Languages (Dutch, French, English) (25.2%) and natural sciences (math, biology, chemistry) (14.8%). Intriguingly, 1 in 3 (33.47%, N=81) of the respondent teachers have never worked as a teacher after graduation. Here, sex does not make

a difference. Although a multitude of reasons were formulated, factor analysis demonstrates five clusters of reasons that best describe the rationale behind the teachers' exit attrition (explaining 52.92% of variance (VE)). The first factor is called 'job satisfaction' (VE=14.03%) and brings together the items that concern the teacher's motivation, enjoyment, expectations, with items concerning difficulties in the teacher-student relation: e.g. bullying by students, class management. The second factor is called 'school support' (VE=13.12%) and relates the items concerning the lack of support of teachers by principals, and colleagues, inadequate induction and difficult or unwelcome tasks. The third factor 'workload' (VE=9.04%) comprises reasons that have to do with time pressure, emotional tiredness and workload (including administrative work), often in the evenings or during holidays. The fourth factor, called 'future prospects' (VE=8.60%) encompasses the prospects for reassignment (after a temporary position), a long-term contract or a permanent position, associated guarantees of income and career growth. The last factor concerns 'relations with parents' (VE=8.13%). Lack of support from parents and conflicts with parents, are the arguments that are important – load highly – for this factor. On average, these five factors score high as arguments for leaving teacher education: future prospects (M=4.00; SD=1.66), parent relations (M=4.00, SD=0.27), workload (M=3.67; SD=0.89), job satisfaction (M=3.58; SD=0.66) and support (M=3.50; SD=0.60). Interestingly, two 'lived' experiences are convincingly more used by teachers' leaving the profession after a period of practice, compared to their colleagues who never enter teaching practice after graduation.

Discussion

Important implications that derive from this investigation, consequently concern ways of effectively dealing with exit attrition. Regarding limited prospects for the future, one may wonder whether the common Belgian tradition of granting permanent 'untouchable' positions to teachers is desirable. Sequential interims and insecurity of jobs of novice teachers are consequences. Alternatively, 'contracts for an indefinite periods' may offer a valid solution. In addition, the profession becomes more attractive if extra job opportunities or 'stepping stones' are created (Cochran-Smith, 2004; Macdonald, 1999). With respect to the lack of support in schools, however, also structural solutions may motivate teachers to stay, such as mentoring programs (Ingersoll & Smith, 2003). As such, teachers will experience less disappointed expectations. Here, sufficient teaching practice during pre-service teacher education is necessary (Kyriacou & Kunc, 2007). All with one purpose, namely establishing the contrary answer to the original question 'Being a teacher? Yes, I'd love to!'...

PAPER PRESENTATION

Sharing experienced teachers' pedagogical practices with ICT to less-experienced colleagues

Minna Lakkala, University of Helsinki, Finland; Liisa Ilomäki, University of Helsinki, Finland

Several studies address the problem that pedagogically meaningful usage of information and communication technology does not seem to spread easily; new easier and peer-to-peer practices for teacher training are needed. One possible solution is to promote the transformation of experienced teachers' well-tried and cultivated practices to other teachers. The present study includes an experiment where two experienced primary school teachers supported their less-experienced colleagues in designing and implementing an educational unit with ICT. Experienced teachers' classroom practices were documented in materials (a written pedagogical scenario and related videos), which then were used in a tutoring process where the experienced teacher supported a colleague to implement similar practices. The first case was an inquiry project in biology, the second case focused on the practices of virtual publishing through making a Web journal. The pedagogical infrastructure framework, including technical, social, epistemological and cognitive component, was applied for comparing the pedagogical practices with ICT of the more- and less-experienced teachers as well as for evaluating the possibilities and challenges of transferring the practices through materials and tutoring. The results revealed that the expert model and tutoring from the more-experienced colleague encouraged and promoted the tutored teachers to try pedagogical practices that they would not have tried otherwise. Good

technological skills as such are not sufficient for teachers to develop their pedagogical practices with ICT, but other competencies for organizing and guiding pupils' learning activities with ICT in integrated and coherent ways are needed.

Introduction

Modern technologies are considered providing new, valuable possibilities for education. Yet research results indicate that pedagogical change in schools through information and communication technology (ICT) has not actualized as expected. Technology is still used infrequently, only by some teachers and often for prevailing pedagogical methods like sharing information or doing simple exercises instead of advancing collaborative work, creative activities, solving of complex problems, and supporting students' knowledge management skills (OECD, 2010; Smeets, 2005). In teacher training programs, technology, pedagogy and subject domain content are often separated, which does not necessarily provide teachers with competencies for integrating them adequately in classroom practice (Hyo-Jeong & Kim, 2009). Research findings indicate that teachers benefit from concrete examples about using ICT in teaching and from the integration of technical and pedagogical training (Condie et al., 2007; Pedersen et al., 2006). To develop new models for in-service teacher training we tested a model where experienced teachers supported less-experienced colleagues to implement ICT in their classroom practices through authentic examples and tutoring. The main idea was especially to spread examples that represent challenging pedagogical approaches, including rich use of technology and complex activities, and are based on experienced teachers' well-tried and cultivated practices. The aim of the study was to examine how two experienced primary school teachers supported their two less-experienced colleagues in designing and implementing an educational unit with ICT. The Pedagogical Infrastructure Framework, including technical, social, epistemological and cognitive component (Lakkala, 2010), was used as an analysis framework for comparing the pedagogical practices with ICT of four teachers as well as for evaluating the possibilities and challenges of transferring the practices through materials and collegial tutoring. We divided a teacher's role in setting up technology-enhanced collaborative educational settings in two main tasks: 1) Planning, organizing and structuring the overall activity by establishing the underlying pedagogical infrastructure conditions for the collective effort (overall design); and 2) participating in the activities as a guide and expert who provides adapted, situation specific guidance for the learners when needed (scaffolding). In the present study, both the overall design solutions and the scaffolding activities of the more- and less-experienced teachers were examined through the components of the Pedagogical Infrastructure Framework.

Research methods

The general methodological approach was multiple case study where two practice transfer processes between more- and less-experienced teachers concerning teaching with ICT were investigated. The cases represented the Finnish cases in an EU-supported project FICTUP (<http://www.fictup-project.eu>). The aim of the project was to create training materials (written scenarios and related videos) describing concrete pedagogical activities using ICT, experimenting with a close tutoring process among experienced and novice teachers, and providing training institutions with recommendations. The two experienced teachers were knowledgeable in the pedagogical use of ICT, they both trained other teachers to use various applications in teaching, and they had participated in various development projects. They both had also previously collaborated with educational researchers, and they were chosen for FICTUP because of their expertise in the pedagogical use of ICT. The cases represented the teachers' ordinary practices. The less-experienced teachers were the experienced teachers' younger colleagues in the same school. They had used ICT somewhat in their teaching but had not used the specific tools and practices applied in the example scenarios. The first case was an inquiry project in biology, the second case focused on the practices of virtual publishing through making a Web journal. All lessons constituting the pedagogical units conducted by the four teachers were observed and videotaped by one or two researchers. The teachers were shortly interviewed before and after each lesson, asking a few questions about it. An in-depth final interview was carried out at the end of the process. We also collected all documents, writings and other outcomes produced by the teachers and the pupils during the process in the virtual spaces and the Web. The primary data used in the study were the videotaped lesson observations, because we wanted to focus on the teachers' real practices in the classroom. All videotapes were examined and sections revealing the teachers' overall design solutions or scaffolding practices were categorized qualitatively using the components of the Pedagogical Infrastructure Framework. Other data were used as complementary source for interpreting the classroom activities and providing examples of the overall design and scaffolding practices of the teachers.

Results

Concerning the tutoring, the scenario descriptions and especially the videos were useful in orientating tutored teachers in new pedagogical practices with ICT, but still the most important support for the tutored teachers was discussions with the experienced teachers. The tutored teachers reported that the models and tutoring from their more-experienced colleague encouraged and promoted them to try pedagogical practices that they would not have tried otherwise. The comparison of more- and less-experienced teachers' pedagogical usage of ICT revealed clear

differences. Experienced teachers planned more long-term, goal oriented working processes consisting of well-organized activities where the various elements of pedagogical infrastructure were taken care of and smoothly integrated. In their units, the usage of technology served the overall goal and the activities provides pupils with a possibility to practice challenging technical and academic skills in a meaningful context. The overall designs of their less-experienced colleagues were not as integrated and coherent. In their scaffolding, they emphasized technological and content-related issues, whereas the organization of social aspects (pupils' collaboration) and especially the promotion of pupils' cognitive, metalevel awareness of the practices were less-evident.

Conclusions and educational significance

It is important that teachers share their tacit expert knowledge through personal connections, such as tutoring practices, for encouraging less-experienced teachers to use ICT in their teaching. It is necessary to understand the differences in pedagogical practices between more- and less-experienced teachers in order to better support less-experienced teachers in their difficulties. The study confirmed results of our previous studies (Ilomäki, Lakkala & Paavola, 2006) that technological skills as such are not sufficient for teachers to develop their pedagogical practices with ICT, but other competencies for planning, organizing, structuring and guiding pupils' learning activities with ICT in integrated and coherent ways are needed.

PAPER PRESENTATION

Do they really become smarter? The development of lesson planning ability in internships

Karl-Heinz Arnold, Universität Hildesheim, Germany; Andreas Bach, University of Hildesheim, Institute of Educational Science, Germany; Sarah Brodhacker, University of Hildesheim, Institute of Educational Science, Germany

During the university phase of teacher education, teacher students in Germany take part in a series of subsequent internships. Primary internships cover general aspects of classroom teaching and learning while internships in the second part of teacher education programs provide for subject specific teaching competence. Primary internships are mostly linked to studies in general school pedagogy including as a major part the German Tradition of General Didactics (Klafki; Schulz) which serves as a comprehensive theory of classroom teaching and student learning. Teaching competence is considered to evolve in applying Didactics' knowledge to the planning of a lesson and the subsequent analysis of the lesson delivered.

The research project ESIS (Entwicklung Studierender in Schulpraktika, engl.: Teacher Student Development in Internships, TSDI) assesses the ability to plan, deliver, and analyze lessons as it develops during two subsequent general internships in the university phase of teacher education. Although internships are highly appreciated by teacher students, only small learning gains occur. This can be explained partly by moderating effects of teacher self-efficacy that seems to slow down the self-appraisal of teaching ability. Internships also provide a more realistic view on the considerable demands of classroom teaching.

Internships can be conceptualized within the generic framework of professional teacher competencies spelled out by Baumert and Kunter (2006). Four aspects are distinguished: (a) beliefs/value orientations; (b) motivational orientations; (c) self-regulatory abilities; (d) professional knowledge. Following Shulman (1986), teachers' professional knowledge can be subdivided in five areas: (1) pedagogical knowledge; (2) content knowledge; (3) pedagogical content knowledge; (4) organizational knowledge; (5) advisory knowledge (cf. Baumert & Kunter 2006).

Pedagogical internships in the first phase of German university teacher education require students to apply mainly pedagogical knowledge (in German: Allgemeine Didaktik, Paedagogik) and to some extend also organizational knowledge (in German: Schulpaedagogik) whereas subsequent internships that focus on subject matter teaching mainly draw on content knowledge (in German: Fachwissenschaft) and its pedagogical aspects (pedagogical content knowledge; in German: Fachdidaktik). Teacher students' beliefs and motivational orientations function as variables mediating knowledge application in teaching experiences and knowledge acquisition by observing mentor teachers.

Teacher competencies can be assessed either by objective (distal indicators: cf. Kennedy et al., 2008; proximal indicators: e.g. TEDS, cf. Bloemeke, Kaiser & Lehmann 2010) or subjective approaches (e.g., self-ratings; cf. Frey, 2008; Rauin & Maier, 2007). Combined approaches also have been employed (e.g. COACTIV; cf. Krauss et al., 2008; Baumert et al., 2010).

In the so called German tradition, pedagogical knowledge on teaching and learning is framed by theories and models of "General Didactics" (cf. Westbury, Hopmann & Riquarts, 2000). The Bildung-centered resp. Critical-constructive approach of Klafki (1994) and the Learning-centered resp. Teaching-centered approach of Schulz (1965; 1980) are considered as the two major approaches in General Didactics. Internships in the first phase of university teacher education offer teacher students opportunities to observe and analyze classroom teaching (and learning). The second step is to plan lessons and to deliver the planned lesson which is followed by analyzing the lesson delivered. Both

planning and analyzing a lesson is bound to the theoretical background of planning models within the framework of General Didactics (cf. Arnold & Koch-Priewe in press). The provision of detailed written lesson plans seems to be a typical feature of student teacher internships. However, it can be shown that expert teachers do implicitly draw on the planning categories of Klafki's model (cf. Koch-Priewe, 2000).

The present study (Teacher Student Development in Internships, TSDI; in German: Entwicklung Studierender in Schulpraktika, ESIS) analyzes both intended and unintended effects of internships. Cumulative learning effects should occur during and between succeeding internships. Moderating effects of student characteristics (i.e. self-efficacy) are investigated.

Method

At the Hildesheim university, the teacher education program encompasses three phases of general pedagogical internships during the first three semesters and two subject matter related internships in the last quarter of the four year program. An entire cohort of 400 students is assessed after the completion of each of the three pedagogical internships. Students start with two subsequent one-day-a-week internships. In the first part they observe and analyze lessons delivered by the mentor. In the second part they themselves plan and deliver lessons that are analyzed afterwards by themselves, their fellow students, their mentor, and their university tutor. The students take also part in an assessment at the beginning of the first practicum and before entering the second major practicum. The second practicum, a four weeks in-a-block internship after third semester, is mainly supervised by the mentors. At least, to investigate long term effects a follow-up assesment is conducted three months later.

To capture learning gains, a self-assessment questionnaire has been developed measuring the ability to plan, deliver, and analyze a lesson (Lesson Planning, Implementation, and Analysis; LPIA) on the basis of the major models of General Didactics. The instrument comprises 16 items within three subscales representing the postulated three dimensional structure (planning, delivering, and analyzing a lesson) quite well (CFA satisfactory fit-indices, Cronbach's alpha ranging from .80 to .87 for the subscales, .93 for the total scale). Additionally, an achievement test is being developed measuring the ability to plan, deliver, and analyze a lesson by answering multiple-choice questions to vignettes that cover typical situations of teacher decision making on lesson planning and delivering and planning based lesson analysis.

Teacher self-efficacy beliefs (TSEB) are measured by using the 10-item scale provided by Schwarzer and Schmitz (1999). Data are analyzed within the framework of structural equation modeling. The LPIA-questionnaire can be integrated in the measurement model by its three subscores. Because it may be that not only learning gains but also losses may occur, latent-change modelling is employed. The teacher student self-efficacy is introduced into the measurement model by parcelling (subscores for the first and second half of the 10 items).

Results

First results at the descriptive level show moderate learning gains over four points of measurement and also a decrease of variance. Further data analysis using the mplus-software (Muthen & Muthen, 2010) is in progress.

PAPER PRESENTATION

Peer feedback in secondary education: Effects of peer-feedback training on learning

Jan-Willem Strijbos, Ludwig-Maximilians-Universitat, Germany; Dominique Sluijsmans, HAN University of Applied Sciences, Netherlands

The increased application of student-centered learning emphasises that students assume responsibility for their learning. Peer assessment is well-suited in this respect. Although peer assessment researchers stress the role of feedback, the evidence for peer-feedback effects is scarce. A recent study by Strijbos et al. (2010) investigated the impact of peer-feedback content (concise general (CGF) vs. elaborated specific (ESF) and sender's competence level (low vs. high) on peer-feedback perceptions and revision performance. ESF was perceived as more adequate than CGF and feedback by a high competent peer as more adequate than feedback from a low competent peer. Other recent studies examined the content of peer-feedback comments. Non-directive feedback was found to predict more complex revision (Cho & MacArthur, 2010) and justification improved revision performance (Gielen et al., 2010). In this study the effect of a training in peer-feedback is investigated. More specifically whether a training in providing CGF or ESF affects peer-feedback perceptions and revision performance differently compared to students receiving no

training. Forty-eight Dutch pre-university secondary education students were trained in providing CGF (N = 17), ESF (N = 17) or received no training (N = 14). Both peer-feedback conditions provided more comments than the control group. The ESF group wrote longer (elaborated) feedback compared to the CGF group. No differences were found for learning outcomes, however, consecutive experiences of CGF might be perceived as less adequate and decrease affect over time. In addition, consecutive experiences of CGF and ESF do not automatically increase application of comments.

The increased application of student-centered learning emphasises that students assume responsibility for their learning. Peer assessment is well-suited in this respect. Although peer assessment researchers stress the role of feedback, the evidence for peer-feedback effects is scarce. A recent study by Strijbos et al. (2010) investigated the impact of peer-feedback content (concise general (CGF) vs. elaborated specific (ESF) and sender's competence level (low vs. high) on peer-feedback perceptions and revision performance. ESF was perceived as more adequate than CGF and feedback by a high competent peer as more adequate than feedback from a low competent peer. Other recent studies examined the content of peer-feedback comments. Non-directive feedback was found to predict more complex revision (Cho & MacArthur, 2010) and justification improved revision performance (Gielen et al., 2010).

Purpose and research question

In this study the effect of a training in peer-feedback is investigated. More specifically whether a training in providing CGF or ESF affects feedback perceptions and revision performance differently compared to students receiving no training.

Method

Participants. The participants were 48 Dutch pre-university secondary education students of which 22 were boys and 26 girls (Mean age = 15.6).

Design and materials.

A quasi-experimental intervention was conducted with two experimental conditions and a control group. One-third of the students were trained in providing CGF (N = 17), one-third in providing ESF (N = 17) and one-third received no training (N = 14). Subsequently they wrote three business letters of complaint (unsolicited ringtone subscription, unsolicited gym subscription, torn pair of jeans). Each student received anonymous peer-feedback on each letter. Next they first applied the peer-feedback and subsequently rated the peer-feedback in terms of 'Perceived Adequacy of Feedback' (PAF), Willingness to Improve (WI) and Affect (AF) (Strijbos et al., 2010). School criteria (content, format, style, spelling) were used to assess the quality of the letters and revisions (interrater reliability: $\tau = .77$, p p

Procedure.

Prior to the intervention students first completed a baseline task (20 minutes). Next they received the training. Students were prompted to provide CGF, ESF or received no training (25 minutes). Subsequently they wrote the first letter (L1) (35 minutes) and provided anonymous peer-feedback to a fellow student (15 minutes). Subsequently they applied (20 minutes) and rated the feedback in terms of PAF, WI and AF. The same procedure was used for the second (L2) and third (L3) letter.

Results

Manipulation check. The control group provided the least and shortest comments (143 comments; 632 words). Students in the CGF condition provided 370 comments using 1318 words and the ESF group 306 comments using 2748 words. Both feedback conditions provided more comments than the control group. The ESF group wrote longer (elaborated) feedback compared to the CGF group.

Feedback perception.

All scales were sufficient to highly reliable for all assignments (L1: PAF $\alpha = .88$, WI $\alpha = .59$, AF $\alpha = .79$; L2: PAF $\alpha = .89$, WI $\alpha = .84$, AF $\alpha = .83$; L3: PAF $\alpha = .88$, WI $\alpha = .74$, AF $\alpha = .82$). A repeated measures ANOVA revealed no significant differences for PAF on the first and second letter, but a significant difference for the third letter, $F(2, 42) = 4.62$, $p = 0.15$, with the CGF group reporting the least perceived adequacy. No significant differences were found for WI. A repeated measures ANOVA for AF revealed a trend, $F(2, 42) = 2.37$, $p = .83$, with the CGF group reporting less positive affect after the third letter compared to the first letter.

Learning outcomes.

There were no significant differences between the research conditions in terms of the revision performance over time. However, all students improved over time signified by the difference between the first and third letter, $F(1, 43) = 26.45$, p

Peer feedback content.

Students in the ESF condition provided positive remarks in 45% of all cases, compared to 30% in the CGF condition and 17% in the control group. Students in the ESF condition provided a suggestion for improvement in 66% of all comments, 62% in the control group and 55% in the ESF condition. An explanation is provided by the control group in 20% of all comments, followed by 28% in the CGF condition and 55% in the ESF condition. When asked via self-report whether they applied the peer-feedback the control group indicated that they applied 90%, the ESF group 79% and the CGF group 76%. However, analyses of actual application revealed that the control group still applied comments most often but only for 54% of all comments (36% less compared to self-report), the CGF condition in 35% and the ESF condition in 36% of all cases. Application increases over time for the control group (L1 = 46%, L2 = 52%, L3 = 67%), whereas it decreases for CGF (L1 = 44%, L2 = 40%, L3 = 21%) and ESF (L1 = 42%, L2 = 38%, L3 = 26%).

Significance of this study

This study shows that students can be trained to provide specific types of feedback during a peer-feedback exercise. Although we did not find differences in learning outcomes, the results illustrate that consecutive experiences of CGF might be perceived as less adequate and decrease affect over time. In addition, consecutive experiences of CGF and ESF do not automatically increase application, which might be due to recipients identifying the incorrectness of a comment or recipients simply disagreeing despite its correctness. Students' arguments for applying comments requires closer scrutiny in follow-up studies.

PAPER PRESENTATION

Examining Media-Effect among Subgroups of Students with Different Ability Levels

Krisztina R. Toth, German Institute for International Educational Research, Germany; Gyongyver Molnar, University of Szeged, Hungary; Agnes Hodi, University of Szeged, Hungary; Beno Csapo, University of Szeged, Hungary

Due to the innovative possibilities provided by computers and the cost-efficiency of the system, technology-based assessment should displace paper-based testing (Csapo, Latour, Bennett, Ainley, & Law, 2010). If computer-based assessment is applied to replace traditional testing a number of questions arise regarding media-effect (see e.g. Clariana, & Wallance, 2002). In the past several media-effect studies were carried out focusing on different student and item-related variables, some of these studies attempted to identify the effect of background variables (gender, race/ethnicity, and ICT related factors) for the differences between paper- and computer-based test performance, however, less attention has been paid to the examination of paper-and-pencil test performance of different sample subgroups. The purpose of this paper is to investigate a comparison of data derived from two test delivery among subgroups of students based on paper-and-pencil performance. This paper argues that the media-effect is related to the ability level of test takers in low-stakes testing. Various age groups, measured context and research design validate our findings. Results indicate that different ability level students behave differently in traditional and computerized assessment. Low ability students performed significantly better in computerized environment than in traditional testing. The performance of students with average ability level was media independent, or they achieved higher scores in the computerized test delivery. High ability students were disadvantaged in the online assessment. These findings support that the comparison of paper-based and computer-based performance should consider the students' ability level realized in printed medium.

Theoretical background

Computer-based assessment (CBA) has been more and more widespread in every segment of educational assessment, including large-scale international projects, national and regional surveys, and formative and diagnostic evaluation. CBA opens new areas for assessment where technology is essential to define the construct (e.g. ICT literacy). In other

domains where CBA is applied to replace former paper-and-pencil testing, several questions arise (e.g. validity issues) during the implementation phase. This resulted in a number of media-effect studies in the last few years mainly focusing on subgroup analysis based on gender, race/ethnicity and computer familiarity (e.g. Clariana & Wallance, 2002; Bennett, Braswell, Oranje, Sandene, Kaplan, & Yan, 2008) to investigate students who achieve better or worse in the two media. However, less attention has been paid to the examination of different subgroups of the sample based on their performance on paper-and-pencil tests.

Aims

The purpose of this paper is to study the media-dependence of low, mean and high ability-students in different contexts and literacy domains, to control media-effect and make detailed comparisons of test results delivered by different media.

In this paper we

- (1) compare paper-and-pencil (PP) and computer-based (CB) achievements to study media-effect,
- (2) determine the impact of delivery media on low, mean and high ability-students' achievement,
- (3) examine the value of the difference between PP and CB achievement among subgroups.

Methods

The present analyses synthesize the results of three PP and three CB data collections aimed at measuring students' inductive reasoning and reading skills. The sample ($n=2398$) for the analyses was drawn from 4th to 6th graders (10 to 12 year-old). Different research design was applied in all cases. In the first study identical versions of a 58 item inductive reasoning test were administered to the same sample of 5th graders in printed and online formats. The test comprises three subtests: number analogies (14 open-ended items), number series (16 open-ended items) and verbal analogies (28 multiple choice items). In the second study identical versions of two different inductive reasoning tests were administered to a different sample of 4th, 5th and 6th graders and in the third study the same 6th graders took parallel reading comprehension tests in the two media. To characterise student-level differences in the second study match sample design was employed based on region, type of settlement and gender. The computer-based test versions were delivered via Internet with the TAO (Testing Assisté par Ordinateur – Computer-Based Testing) platform.

To the detailed person-level analyses five groups of students were formed based on their PP test results. The sample of a test was clustered based on the standard deviation and mean of test scores. Students in the first group achieved ? standard deviation lower scores than the mean, to the second group belonged students between ? and ? standard deviation distance below the mean. Students, whose achievement differed from the mean at most ? standard deviation belong to the average-ability (third) group. Examinees above the average ability-level were clustered in two subgroups: students whose average achievement was between ? and ? standard deviation distance above the mean, and high ability-level students achieved the best scores, above ? standard deviation, on the test.

Educational and scientific importance

The history of CBA shows that technology-based testing does not always provide equivalent results to traditional tests. One of the reasons is that solving certain tasks and problems displayed on screen requires completely different cognitive processes than working on paper. Thus to compare findings of different measurements based on various test delivery platforms and to counterbalance the media-effect, the transformation of paper-and-pencil achievements into computer-based performance has to be worked out.

Results and Discussion

The reliability index (Chronbach-?) of the tests varied from .76 to .91 in PP, and between .70 and .91 in CB test administration mode. The delivery mode did not influence the reliability indexes of the tests, however, it affected students' mean achievement. Independent from the measured grades and constructs students' achievement was significantly higher on printed medium.

The subgroup-level analysis based on PP achievements revealed a diverse picture. Students with low-ability level in each tests performed significantly better in computerized environment than during the paper-and-pencil test administration. Contrarily, average-ability students' performance was media independent, or they achieved higher scores during traditional testing than at online data collection. High-ability students were disadvantaged in the online assessment in all testing contexts.

Results indicated that not only the direction of media-effect differs among the subgroups but the value of PP and CB difference as well. The groups of students with the lowest performance in each sample (e.g. inductive reasoning in 4th grade $t=10.43$, $p<.05$) showed high media dependency, low-ability level examinees ($t=2.7$, $p<.05$) were also advantaged by the introduction of the new testing medium in the low-stakes testing. These findings suggested presumably greater persistence during CB testing. The achievement of average-ability students was media

independent ($t=-2.01$, $p=.05$), and the same tendencies ($t=-5.26$, $t=-11.02$, $p<.05$) were outlined in the two clusters of high-ability level test takers than in the low-achievers'.

In sum, subgroup-level analysis pointed out that students with different ability-level behave dissimilar in the two testing environments. Findings based on various age groups, research design and measured constructs observed the same tendencies in the direction and the change of the media-effect value independent from the research methods. These results suggest that the transformation of PP performance into CB achievement should consider test takers' ability-level realized in PP assessment.

PAPER PRESENTATION

Measuring learning outcomes over time in preschool science education

Claus H. Carstensen, University of Bamberg, Germany; Mirjam Steffensky, IPN, Germany; Eva-Maria Lankes, Technical University of Munich, Germany

Recent studies show that preschool children are able to develop scientific knowledge in different content areas (Samarapungavan, Mantzicopoulos & Patrick, 2008). However, little is known about the support of science learning at preschool age. The research project SNAKE compares learning outcomes across different instructional approaches in preschool science instruction. The scientific competencies of preschool children were assessed pre and post an instructional treatment as well as in a later follow up. In this paper the competence tests used for the three assessments will be outlined and the scaling and linking procedures will be reported and their results and appropriateness will be discussed. We report on the successful construction of a test for science competencies of preschool children to assess gains during experimentally varied instructions. We described and analyzed change in science competencies with respect to the experimental variation.

Measuring learning outcomes over time in preschool science education

Recent studies show that preschool children are able to develop scientific knowledge in different content areas (Samarapungavan, Mantzicopoulos & Patrick, 2008). However, little is known about the support of science learning at preschool age. The research project SNAKE compares learning outcomes across different instructional approaches in preschool science instruction. The scientific competencies of preschool children were assessed pre and post an instructional treatment as well as in a later follow up. In this paper the competence tests used for the three assessments will be outlined and the scaling and linking procedures will be reported and their results and appropriateness will be discussed.

Introduction & Questions

Within the project key questions are what instructional support is most helpful for preschool children to improve their understanding of scientific concepts from everyday knowledge towards scientific literacy. Within an experimental variation, the effect of hands-on activities, cognitive reflection and a combination of both as well as a control group with non scientific instruction and a control group without instructions are compared to each other.

The assessments of scientific competencies were constructed with regard to "water" as topic, and more precisely, focusing on the processes of melting and freezing, of condensation and vaporizing and (rather exploratory) of chemical solutions, since all preschool children will presumably have a good everyday knowledge of many of the related phenomena. The assessments as well distinguish between conceptual knowledge and some elements of knowledge about scientific methods. A third characteristic of the tasks was whether children are required to think of potentially everyday observations or activities in contrast to rather abstract cognitive operations.

To assess of scientific competencies a test was developed for each of the pre test, post test and follow up. The test were constructed as structured interviews asking the children to either point to the relate picture to concepts, choose the correct option or produce a short open response. The post test and follow up test used anchor items from the previous test as well as new items to match the competence level of the children in each assessment. We were able to

show that with the test for the first assessment we obtain a one-dimensional competence scale based on 29 homogenous items with a reliability of .75 and a sufficient variance to discriminate between children with higher or lower competence.

In this paper, questions of modeling a single competence from the different assessments will be addressed. Does every test measure a single competence? Do the three tests measure the same construct? How can the three assessment be linked onto the same metric?

Method

The responses to the test were scored 0, 1 or 2 points for wrong, partially correct or correct responses respectively. Note that only for about half of the items the partial credit was appropriate. To scale the item responses the ordered partition model OPM (Wilson 1992) was used. The OPM generalizes the partial credit model (Masters 1982) for data where categories are only partially ordered. In consequence, not every category may be observed and thus the model is able to handle missing categories.

Scale analyses were performed within each assessment, the fit of the models was evaluated using item fit statistics and comparing item difficulty parameters for different groups according to gender and score in science and cognitive abilities. To investigate whether the assessments measure the same construct, two-dimensional models with anchor items as one dimension and time specific items as second dimension were estimated and compared to one-dimensional models with CAIC, a likelihood based statistic for global fit.

To establish a link between the three time points, an item response model for longitudinal data (Embretson 1991) was fitted to all data simultaneously. The software used for all item response analyses is Conquest (Wu et al. 1997).

Results

For each assessment an OPM was found to fit the data with sufficiently high reliability of .75 for the first assessment, .80 for the second and .82 for the third, computed from point estimates (WLE). The observed variances indicate a sufficient discrimination between the children's competencies. The link between the scales was successfully established and change over time will be presented descriptively as difference between adjacent time points as well as through covariance analyses of the post-test and follow up assessments with regard to the experimental groups controlling for pre-test and cognitive abilities. For example, analyzing post-test results, only the experimental group with the combined instruction of hands-on activities and reflection showed a significantly higher increase in competency than the control group whereas in the other two experimental groups the gains were not bigger than in the control groups.

Discussion

With this presentation we report on the successful construction of a test for science competencies of preschool children to assess gains during experimentally varied instructions. We described and analyzed change in science competencies with respect to the experimental variation.

PAPER PRESENTATION

A multimodal analysis on consistency and item effect on children's astronomical conceptions

Cinzia Ronchi, Roma Tre University, Italy; Paola Perucchini, Roma Tre University, Italy

The present research was focused on analyzing consistency in children's understanding about the Earth, day-night cycle and seasons and on detecting if such conceptions could be affected by the item kind, as some authors suggested (Siegal et al., 2004; Vosniadou et al., 2004; Nobes et al., 2005; Straatemeier et al., 2008).

We found that primary school children express consistent conceptions about the shape of the Earth, as Vosniadou and Brewer (1992) previously found, while only a few of them held consistent conceptions about gravity. Similarly, not many children expressed consistent conceptions about day-night cycle and the seasons' cycle.

We also found that the item kind could affect children's responses, since it resulted that children generally scored significantly better after a forced-choice item than after an open-ended item for all investigated conceptions, as Siegal (et al., 2004) and Nobes (et al., 2005) argued. Children also scored significantly better further to item containing a factual question than an inferential question and further to item based on a geocentric perspective than on an external-to-Earth perspective, except for season's cycle conceptions.

In the current debate about conceptual change in astronomy domain, three main theoretical perspectives are present, each one elaborating an explanation about the nature and the development of children's ideas and about the proper instruments to investigate them. Authors following the mental models perspective (Vosniadou and Brewer, 1992; 1994; Samarapungavan et al., 1996) argue that children held a few consistent mental models built on the basis of experience and that only by reinterpreting the entrenched preconceptions which originated such models a child can understand the scientific model. On the contrary, authors following the fragmented knowledge approach (diSessa, 1998; Nobes et al., 2003; Nobes et al., 2005) claim that children's knowledge is initially constituted by unconnected pieces of knowledge, deriving from simple abstractions of everyday experience, and that the gradual acquisition of culturally-accepted scientific pieces of information would create links and connections until arriving to the consistency of the scientific notion. Authors following the contextual-based perspective (Caravita and Hållden, 1994; Shultz et al., 2001; Larsson and Hållden, 2009) suggest that conceptual development may be seen not only in terms of a concept substitution, but also as a possible coexistence of both intuitive and scientific conceptions in child's conceptual structure, who gradually would learn to use them consistently across different contexts (Caravita and Hållden, 1994; Larsson and Hållden, 2009).

With reference to the assessment methods, studies following the mental models perspective (Vosniadou and Brewer, 1992, 1994; Samarapungavan et al., 1996; Vosniadou et al., 2004; 2005) generally use a semi-structured interview protocol, mainly constituted by generative open-ended questions – also called inferential by Lightman and Sadler (1993) – which would allow the researcher to discover the mental model which is behind child's responses. Authors following the fragmented knowledge approach usually use forced-choice questioning methods based on adapted versions of Vosniadou and Brewer's original interview protocol (Siegal et al., 2004), or on multiple choice of images (Nobes et al., 2005; Straatemeier et al., 2008). Since from these last studies results show a much higher percentage of scientific conceptions than in Vosniadou and Brewer (1992), they argued that the mental models could be in some way connected to an open-ended questioning method or to the poor child's ability in drawing (Nobes et al, 2005). Vosniadou (et al, 2004) explained such differences by assuming that in the case of an open-ended method children's task is to elaborate an explanation, while in the case of a forced-choice method it is simply to recognize the correct responses between different alternative, and does not imply deeply understood it.

Most of the reviewed research investigating children's consistency and item influence concerned the Earth, while a few studies focused on day-night cycle. We did not find any research focusing on consistency and item effect in children's conceptions about seasons' cycle. It could be therefore interesting to compare consistency in conceptions expressed by children about the Earth, day-night cycle and seasons, and to understand if the modality of assessing could affect such conceptions.

Aims of the present study are:

(a) to determine if children's understanding of the Earth, day-night cycle and the seasons is made of consistent conceptions or unconnected pieces of knowledge; (b) to analyze the possible influence of the questioning methods in children's conceptions.

The sample was constituted by 199 primary school children, divided in 5 groups: 39 first-graders (16 female and 23 male, mean age 6,9); 37 second-graders (13 female and 24 male, mean age 7,9); 45 third-graders (24 female and 21 male, mean age 9); 36 fourth-graders (18 female and 18 male, mean age 9,8); 42 fifth-graders (19 female and 23 male, mean age 10,7). All children came from a school located in the suburb of Rome, Italy.

Children were administrated by a 22 item paper-and-pencil test, created on the basis of existing literature (Vosniadou and Brewer, 1992-1994; Baxter, 1989; Lanciano, 1996; Nobes, Martin and Panagiotaki, 2005; Straatemeier et al., 2008; Perucchini and Ronchi, 2008). The test allowed us to examine children's conceptions according to three aspects: the task, since some item required to make a draw or to choose an image; the question, since there were factual and inferential questions; the reference context, since some item were based on a geocentric perspective and other on an external-to-Earth perspective.

We analyzed consistency by comparing conceptual levels which appeared in all item investigating the same conception, and item influence by comparing conceptual levels which appeared according to the task, the question and the reference system.

In our study a big percentage of children consistently assigned the Earth the same shape across all the item of the test, while a lower percentage of them held a consistent conception about gravity. Children's consistency about Earth's shape significantly increased with age.

A little percentage of children held consistent conceptions about day-night cycle, and even if a higher percentage of children expressed consistent conceptions about seasons, such consistency significantly decreased with age.

Our results on consistency are therefore only partially in line both with Vosniadou and Brewer (1992; 2004) and Nobes and colleagues (2003; 2005) because even if children were mostly consistent about the shape of the Earth, their conceptions about day-night cycle and seasons were substantially inconsistent. Consistency in children's conceptions about seasons even decreased with age.

Concerning item effect, we found that children had higher scored when assessed with a choice-of-images item than with drawing-item and these results may confirm Nobes's hypothesis (et al., 2005) of a connection between the appearance of mental models and the poor child's ability in drawing. We also found that children generally showed more advanced conception when received a factual question than an inferential question, confirming therefore Siegal (et al., 2004) and Nobes (et al., 2005) findings. Moreover, children scored significantly better to item based on a geocentric perspective, while there was no difference in the case of seasons according to the reference system.

PAPER PRESENTATION

Attention and working memory as predictors of the formal thinking and school achievement

Risto Hotulainen, University of Helsinki, Finland; Helena Thuneberg, University of Helsinki, Finland; Jarkko Hautamaki, Helsinki University, Finland; Minna Kyttala, University of Turku, Finland

Our ability to remember locations in space (visuo-spatial working memory) and our ability to direct attention to those locations (attention) are two fundamental and closely related to developing cognitive processes. These developing cognitive processes can be seen within the Piagetian tradition as transitions through different levels of cognitive operations. These abovementioned variables are shown to make contributions to learning both by themselves and by meditating through other introduced variables. In our study we examine these effects by gender and age variation. The sample consisted of ninth-graders (N = 112, n=47 males, n=65 females; mean age 15,26 years) from 7 classes in the capital area in Finland. The path analyses showed the most powerful single predictor of the school achievement is cognitive thinking level. Regardless of the fact that attention and working memory both contributed outcome measures: attention effected both working memory and school achievement, and working memory cognitive thinking, in general, they added very little to the predictive validity supplied by cognitive thinking. Age predicted negatively both school achievement and especially in cognitive thinking indicating that the older students were having lower values. The schools have not been able to cover good-mentioned late start. In practice, the delayed start of the school should not be used and accordingly effective prevention and other interventions, especially cognitive ones, are needed.

Summary 1.

Introduction

In this study we present a framework in which we show how attention and working memory contribute cognitive thinking and accordingly school achievement. We assume that attention as measured in easy, prolonged working tasks presents measure of fundamental attentional capacity (Smit & Ven 1995, cf. Spearman 1927). In such meaning, attention should have corresponding effect on both working memory and cognitive thinking. Cognitive development was conceptualized as formal operational thinking, and more specifically on control variable schemata (CVS). The Neo-Piagetian criterion-based methodology has proved to be effective, and the operational thinking stages have been shown to have relevance on cognitive development of adolescence (Adey et al., 2007; Kuhn, 2008; Shayer, 2008).

1.1 School achievement and formal operational thinking. The effect of intellectual factors, measured by traditional intelligence tests on achievement have been confirmed (Gottfredson, 2002; Freudenthaler et al. 2008). Previous

studies have analyzed whether girls have higher scholastic achievements after the effect of the cognitive factor is controlled (Gibb & al., 2008). Here we use CVS as an indicator cognitive thinking when studying parallel effects.

1.2 Improving prediction by using measure of attention Attention is considered to be crucial for learning and it is also claimed to be an important factor of intelligence (Ven 2001). Here we use Attention Concentration Test (ACT) based on the Binocular rivalry theory (Ven et al. 2005) based on the basic assumption, that during the performance of any mental task the subject actually goes through a series of alternating states of distraction (non-work) and attention (work). Acquired measure by the ACT could be considered to be a high-order mental function which affects cognitive processes such as working memory and executive ones, and, thus, connects study of attention to Piagetian study of formal thinking (cf. Russell 1999).

1.3 Improving prediction by using measure of working memory (spatial). According to Baddeley's framework (1986), working memory (WM) both processes and stores information for a short time. Studies have shown that working memory tasks highly predict academic performance in various fields (Holmes & Adams, 2006; Jarvis & Gathercole, 2003). WM is also very closely related to both attention (Kane et al. 2006) and g (Demetriou, et al. 2010).

2. Aims of the study

In the current study, we examine whether variation in cognitive thinking and/or school achievement were each specifically associated with processing variability in working memory (visuo-spatial) and attention tasks. Moreover, the aim was to explore, whether the formal operational thinking equally strongly affected the achievements of boys and girls along with age-effect control. The research questions were:

1. What are the effects of attention and WM (visuo-spatial) on school achievement and CVS?
2. What is the relationship between CVS and school achievement?
3. What is the effect of gender or age group on school achievement and CVS?

3. Methodology and Participants

The sample consisted of ninth-graders (N = 112, n=47 males, n=65 females; mean age 15,26 years) from 7 classes in the capital area. About age variation in Finland: children should start school during the year when they turn seven. Parents of the child are allowed to apply change of the entry year according to psychological tests. There are relatively larger shares of immigrant students than native students among over-aged. Repetition of the class is rare, but possible.

Instruments

The Formal Operations Test is a test of scientific reasoning which measures the mastery of a control of variables. It is a second-generation modified group-version (Hautamäki 2000) of the original Science Reasoning Tasks, The Pendulum (Shayer & Wylam, 1978) based on one of the Inhelder-Piaget identified formal schemata (Inhelder & Piaget, 1958). In the test subjects are comparing F1 drivers, cars, tires and race tracks. Visuo-spatial working memory was measured with matrix task which is based on the tasks created by Wilson, Scott, and Power (1987). The task is expected to probe non-verbal working memory and was used to assess rather passive, short-term storage of simultaneous visuo-spatial information. The Attention Concentration Test (ACT) primarily measures attention or more specifically the attention of concentration (variation of series of reaction times). The test is based on the three assumptions: 1) knowledge should not play a part in the final test score: only simple problems should be used; 2) differences in previous experience with the task should not be allowed, 3) temporal feelings should not play a part: multiple trials. The test is computer-based.

School Achievement referred here as a GPA was an index of school achievement and was computed as a mean of school subjects common to all study subjects.

Analysis procedures

The path analyses were done with the AMOS statistical package (Version 16.1, Muthén and Muthén 1998-2007). The goodness of overall fit of the estimated models was evaluated by four indicators: χ^2 -test, CFI, RMSEA. 4. Findings The predicted model (attention – working memory – CVS – GPA – age – gender) emerged according to theory. Attention predicted ($\beta = .21$) WM (visuo-spatial) and WM predicted CVS ($\beta = .19$) and CVS grade point average (GPA) ($\beta = .52$). Attention predicted ($\beta = .18$) GPA. WM did not predict the GPA rather, its effects were fully mediated by CVS, resulting in a moderate overall prediction (GPA $R^2 = .35$). Age predicted negatively CVS ($\beta = -.36$) and gender (female = 2) predicted ($\beta = .19$) GPA. The resulting model fit the data well ($\chi^2 = 12.01$, $df = 9$, $p = .213$, CFI = .954, RMSEA = .055).

5. Conclusions

In this study we tried to introduce attention and WM (visuo-spatial) as predictive variables for CVS and GPA. The most powerful single predictor of the GPA is CVS. In general, attention and WM scores add very little to the predictive

validity supplied by CVS. Age had negative effect on CVS and GPA. The older students were behind both of the outcome measures. The schools have not been able to cover good-mentioned late start. In practice, the delayed start of the school should not be used and accordingly, more effective before school prevention and other academic interventions, especially cognitive ones, are needed.

PAPER PRESENTATION

Increasing anonymity in peer assessment using an electronic voting system

Ellen Vanderhoven, Ghent University, Belgium; Annelies Raes, Ghent University, Belgium; Tammy Schellens, Ghent University, Belgium

Students involved in peer assessment often state that they don't feel entirely comfortable with publicly evaluating their peers and peer-pressure might cause stress and a lack of accuracy of the assessment. Consequently, anonymity within peer assessment is an issue to consider. This study explores the use of classroom response technology, i.e. the electronic voting system TurningPoint, as a tool for anonymous peer assessment in higher education. Students had to score each others presentations on different criteria with infrared handset transmitters. The aggregated totals of votes were displayed as immediate feed[®]back. The technology appeared to be well-liked by the students. They especially liked the immediate visual feedback and they could also appreciate the fact that they could give their feedback anonymously. Moreover, they also reported to be less influenced by their peers in giving their scores than they were in traditional peer assessment. These results implicate that the use of a classroom response system as a tool for peer assessment can reduce peer pressure by making anonymous and immediate feedback possible in the classroom.

Theoretical background

The notion of assessment, which stresses the learning process and not only the result, is becoming more and more important in education. Different kinds of innovating forms of assessment have arisen, like self-assessment, peer-assessment and co-assessment. These forms of assessment has been shown many advantages.

In this study we will focus on peer assessment. Research has indicated that peer assessment assists students to create higher quality performances, as a consequence of better understanding of assessment criteria which they use when they play the role of assessors (Smith, Cooper, & Lancaster, 2002; Topping 2003). Moreover peer assessment has proven to be an accurate way of assessment, with high correlations between the ratings of peers and those of teachers (Dochy & Segers, 1999). Yet there have been some conditions put forward to guarantee this high accuracy, such as the presence of unambiguous criteria on which to evaluate (Nancy Falchikov & Goldfinch, 2000) and a necessary training in peer-assessment (Slujsmans, Brand-Gruwel, & van Merriënboer, 2002).

Nevertheless Stepanyan, Mather, Jones and Lusuardi (2009) pointed at a disadvantage of peer-assessment. They found that students experience more stress, because they don't feel entirely comfortable with publicly evaluating their peers. Peer-pressure might also cause a lack of accuracy of the assessment (N. Falchikov, 2003; Sung, Chang, Chang, & Yu, 2010).

In this respect, anonymity of the assessor is an important issue to consider because it is found that students are often concerned about that (Draper & Brown, 2004; Stepanyan et al., 2009). However, anonymous assessment within a face-to-face classroom setting is difficult to orchestrate whereas Stepanyan and colleagues (2009) pointed out that the allocation of marks and in-class activities are important in encouraging student involvement. Consequently anonymity within in-classroom peer assessment has rarely been researched.

Classroom response technology, e.g. the electronic voting system TurningPoint, may provide a solution to these given objections. A classroom response system is a system used in a face-to-face setting to poll students by means of individual infrared handset transmitters. The aggregated totals of votes are displayed as immediate feed[®]back. In this way, within peer assessment students can anonymously and immediately submit their score for every given assessment criterion. In this study we will go into the use of classroom response technology as a tool for peer assessment and more in particular we will focus on the impact of anonymity on reducing peer pressure and feeling comfortable with this kind of evaluation.

Methodology and Participants

Participants in this study were 58 third year Bachelor students in Educational Studies at Ghent University. Their mean age was 20,33. Most of them were female (87,5%). They participated as part of an obligatory course. All of the students had already been involved in traditional peer assessment.

Procedure

Students first had to make a set of criteria for evaluation in consultation with their teacher and then got a training in using them. Afterwards, during three consecutive weeks, students had to give presentations, which were evaluated by their peers using this criteria. The classroom response system, i.e. TurningPoint was used to score (1-5) every criterion. Finally, a questionnaire was administered about the students' experiences and attitudes toward peer-assessment using the classroom response system (items used a 5-point Likert-scale).

Results & Discussion

Students liked the use of TurningPoint for peer assessment. They especially liked the immediate visual feedback ($M=4.07$, which differs significantly from the neutral 2.5 on a 5-point Likert scale, $t(57)=15.53$, $pt(57)=13.09$, $pt(57)=11.08$, p

These results implicate that the use of a classroom response system as a tool for peer assessment can reduce peer pressure by making anonymous and immediate feedback possible in the classroom. The visual feedback is well-liked by students as well. In ongoing research, we are further examining the effects of anonymity in terms of accuracy of the scores and quality of the feedback.

PAPER PRESENTATION

Financial literacy of adolescents: Setting the course for a competence-based assessment instrument

Carmela Aprea, Swiss Federal Institute for Vocational Education and Training, Germany

In modern economies, financial literacy, i.e. the ability to reasonably use financial resources, is becoming more and more essential not just for professionals in the sector of investment and banking but for everyone who is responsible for managing financial affairs in everyday life. However, citizens seem not to be very well prepared with respect to the prevailing demands. Thus, the promotion of financial literacy remains a core concern for every educational system. This, in turn, presupposes the availability of adequate tools which allow identifying existing learning needs. The research to be presented here addresses this need by exposing the conceptualisation as well as the drafting and the results from a field-testing of an instrument for assessing financial literacy of adolescents. The conceptualisation of the instrument is funded on a competence-oriented perspective as well as on action regulation theoretical and knowledge psychological approaches. Based on these considerations, in-depth task analyses were carried out and used to develop a draft questionnaire, which was then handed out to a total of 198 students from 8th and 9th grade of four secondary schools. Students' answers were submitted to psychometric item analyses as well as to descriptive and inferential statistical analyses. The results of these analyses indicate an acceptable fit of the current questionnaire. Additionally, they clearly point out students' weaknesses regarding the components of financial literacy. However, given the preliminary status of the research and the relatively small and restricted sample, cautious interpretations as well as further validation of the instrument are needed.

In modern economies, financial literacy, i.e. the ability to reasonably use financial resources, is becoming more and more essential not just for professionals in the sector of investment and banking but for every person who is responsible for managing his or her financial affairs in everyday life. This increasing importance of financial matters is mainly driven by diverse socio-economical factors which are currently challenging most of the European (as well as other industrialized) countries, and which, among others, include structural changes in the financial services and in the labour market, residualisation of the welfare state and demographic change (e.g., Reifner, 2006). However, other than required, citizens of all ages seem not to be very well prepared to effectively cope with the prevailing financial demands, as for example a research study from the OECD (2005) as well as several national or regional surveys conveyed (e.g., Lines & Schagen, 1996). Especially for the poor, this gap between the overarching significance of financial questions on the one hand, and their deficient preparedness on the other, has the potential to further divide them from their more fortunate fellow-citizens. Given this extremely undesirable and politically charged state of affairs, the promotion of financial literacy remains a core concern for every educational system. This necessity, in turn, presupposes the availability of adequate tools which allow identifying existing learning needs. Against this background, the aim of this paper is to expose the conceptualisation as well as the drafting and the results from a first field-testing of an instrument for assessing financial literacy of adolescents. These research activities are part of a research project which is focused on the development and validation of such an instrument,^[1] and particularly incorporate the following theoretical considerations and methodological courses of action, respectively:

(1) The conceptualisation of the intended assessment instrument should not only be free from commercial interests and ideological biases, but – first and foremost – also be based on a theoretically and pragmatically sound specification of the underlying construct. As scholars in the field of financial literacy (e.g., Pang, 2010) recently suggested, this specification should be considered from a more holistic stance, i.e. not only focus on single and detached knowledge portions but integrate behavioural, cognitive, motivational and attitudinal facets. In order to take account of this issue, we decided to adopt a competence-oriented perspective as expressed for example by Weinert (2001). Moreover, we espoused pertinent action regulation theoretical (e.g., Miller, Galanter & Pribram, 1960) as well as knowledge psychological approaches (e.g., Anderson & Krathwohl, 2001). With reference to these sources, we conceive financial literacy as a domain-specific potential that enables a person to effectively plan, execute and control financial activities. As such, it is based on the availability of individual dispositions, i.e. (different kinds of) knowledge, motivations and attitudes etc. In order to further substantiate this first construct definition, we did not only review already available tools for diagnosing financial literacy but also conducted an in-depth task analysis, which led to (a) a refined description of the sequential and hierarchical structure of the different phases of financial activities, and (b) an elaborated characterisation of the cognitive, motivational and attitudinal demands that these phases impose.

(2) Based on these analytical steps, a first draft of an assessment questionnaire was created. This questionnaire is divided into six parts (A-F) and contains subjective (i.e. self-reporting) questions on adolescents' perceived relevance of financial matters (A), their current financial situation (B) and their financial attitudes (C) as well as objective (i.e. performance test) items concerning their ability to effectively cope with the planning, execution and controlling demands of financial activities, including the respective knowledge and skills (Part D-F). The objective test items were inspired by an authentic assessment approach (e.g., Dochy, 2001) and were embedded in a sequence of realistic financial decision tasks. Both, the products of the task-analysis described above and the draft questionnaire were cross-validated by two content experts (one business school teacher and one lecturer in financial economics).

(3) In order to check the feasibility and comprehensibility of the questionnaire as well as to obtain a first validation of the instrument, the draft version was submitted to a field-testing. In this testing, a total of 198 students from 8th and 9th grade of four lower-level (n=101) and mid-level (n=97) secondary schools in Baden-Wuerttemberg (Germany) were involved. This target group is of specific interest with respect to financial literacy, since most of the students are expected to soon start an apprenticeship, and thus will be in charge of financial independence and responsibility. About one half of the participants were female and their age ranged from 14 to 17 years. According to the curricula, all of them should have mastered the basic (e.g., mathematical) prerequisites necessary to answer the test items. The compilation of the 16 page questionnaire took place during normal classes and encompassed about 60 minutes. Students' answers were submitted to psychometric item analyses. Moreover, descriptive and inferential statistical analyses were conducted. Except for a few items, the results of these analyses indicate a quite acceptable fit of the current questionnaire. Additionally, they clearly point out students' weaknesses regarding the components of financial literacy (e.g., compound computation of interest, risk assessment).

Given the preliminary status of the research and the relatively small and restricted sample, cautious interpretations as well as further validation of the instrument are needed. In the long term, however, the research data should be able to inform curriculum and instructional design as well as educational policy in European countries.

PAPER PRESENTATION

The 'mixed bag' of electronic portfolios: Can they be a form of standardized assessment?

Eva Bures, Bishop's University, Canada; Alexandra Barclay, Mount St. Vincent University, Canada; Philip Abrami, Concordia University, Canada; Elizabeth Meyer, Concordia University, Canada; Vivek Venkatesh, Concordia University, Canada

This study explores electronic portfolios' potential to assess student achievement across diverse classrooms, as do standardized tests including the Canadian Achievement Test (CAT). Assessment tools to measure SRL and literacy were developed and their inter-rater and validity were explored. The tools were applied to portfolios across two years, with $n=369$ participants in grades 4, 5 and 6. The tools included a holistic rubric which assigns a mark from 1 to 5 to SRL and literacy, and an analytical rubric measuring multiple sub-scales of SRL and literacy. During the first year Cronbach's alpha ranged from 0.70 to 0.79 for literacy and SRL overall, but some sub-scales were unacceptably weak. Preliminary results from the second-year analyses show improvement in Cronbach's alpha overall and especially for the sub-scales, partially reflecting improved implementation of the portfolios. Validity was explored by comparing the relationship of portfolio scores to other measures, including the government scores on the CAT4s, the scores we assigned to the CAT4s using our assessment tools, and scores on the SLSQ. The first year portfolio literacy scores correlated ($p<0.01$) to scores we assigned the CAT4s using our assessment tools, and to government preCAT4 scores, but the self-regulatory learning scores did not correlate to our measure of student's self-regulation.

Aims

One exciting aspect of technological pedagogical evolutions for assessing students are electronic portfolios: they can measure learners' literacies, content knowledge, and self-regulatory skills. As institutions lean away from standardized assessment, portfolios are appealing because they allow learners to choose work that showcases their learning. Portfolios may be a more accurate reflection of students' achievements at university (Chambers & Wickermsham, 2007; Zeichner & Wray, 2001) and at K-12 (Barrett, H. 2007). This study explores how to assess electronic portfolios across diverse elementary classrooms, investigating the potential of EPs as an alternative form of standardized assessment. PerspectivesPortfolios allow more authentic assessment than traditional paper-and-pen tests, which may not reflect the student's real abilities (Herman, 1992; Reeves, Herrington, Oliver, & Woo, 2004). EPs allow learners to substantiate their abilities by selecting evidence, reflecting real-life practices (Stiggins, 2002; Frey & Schmutt, 2007). Portfolios allow students to demonstrate the development of their literacy. EPs additionally allow learners to represent their understandings in multiple ways including voice and audio recordings, fitting with evolving conceptions of literacy (Carbonara, 2008). EPs may be linked to a learner's ability to self-regulate their learning (Wade & Abrami, 2005; Zeller & Mudrey, 2007; Hillyer & Ley, 1996). Self-regulated learners are individuals who are metacognitively, motivationally, and behaviourally active participants in their own learning (Zimmerman, 2002). To assess portfolios the literature recommends teacher/student portfolio conferences and rubrics. Numerous rubrics have been developed but inter-rater and validity are rarely explored. Can we develop assessment tools which provide

consistent results such that EPs from diverse classrooms could be assessed, offering an alternative form of standardized testing?

Research Questions:

- 1) Do our assessment tools have inter-rater reliability?
- 2) Do our assessment results correlate to other measures of literacy and SRL skills?

Research Methods & Participants

Participants are volunteer students in grades 4, 5 and 6 across several Canadian provinces whose parents have signed consent forms. Portfolios were created across two years, 2007-2008 and 2008-2009. During year one, a range of implementation was observed within 7 experimental classes ($n=149$). Our analyses drew on 3 classes where both SRL and literacy were assessable, $n=53$. In the year 2008-2009 the portfolios were better integrated so all schools were included in the analysis ($n=220$). Some individual portfolios were excluded, leaving $n=198$ portfolios in analyses. Data Sources The key data source are the EPs. All portfolios are made using ePEARL, a tool designed at the Centre for the Study of Learning and Performance (CSLP). See: <http://grover.concordia.ca/epearl/promo/en/epearl.php> The CAT-4 is the current version of the Canadian Achievement Tests (CAT). One part aims to measure literacy through 2 open-constructed tasks. The Student Learning Strategies Questionnaire (SLSQ) developed at the CSLP measures students' learning strategies.

Consultants.

Feedback from consultants was received via e-mail.

Design

This classroom-based research draws on qualitative and quantitative approaches. Tools were developed to assess the portfolios across several classrooms, exploring their inter-reliability and validity. Each portfolio is double-coded and the inter-rater reliability is explored. The same tools are applied to the CAT4s. Validity is explored looking at the relationship of portfolio scores to other measures, including the government scores on the CAT4s, the scores we assigned the CAT4s, and scores on the SLSQ.

Results and Discussion

After a preliminary attempt and failure, the tools were re-designed with feedback from literacy and assessment consultants from Quebec, Alberta and Manitoba and in light of our results. The completed tools include both a holistic analysis of literacy and SRL and an analytical rubric with 7 writing sub-scales and 3 SRL sub-scales. See Figure 1.

Inter-rater reliability:

We found a range of Cronbach Alpha scores in the high 70's for literacy and SRL. (Table 1). The SRL sub-scales show issues especially with strategies and reflection but this improves. (Table 2.) The literacy sub-scales display problems with two categories, 'voice' and 'organization and sentences,' which improved considerably in 2008-2009. (Table 3).

Validity of Literacy Assessment

Do our assessment tools relate to other measures of literacy? Our analyses are not complete for 2008-2009. For 2007-2008, the holistic scores for literacy correlated (p The rubric portfolio scores for literacy correlated to the holistic and rubric scores we assigned the CATs ($r=.603$ and $.479$ respectively). The holistic and rubric portfolio scores correlated to government pre-CAT scores ($r=.550$), but not the post-CATs.

Validity of Assessment of SRL

Do our assessment scores relate to other measures of SRL? Neither the holistic nor the rubric portfolio scores for SRL correlated to the SLSQ. The scores for SRL in the portfolios correlated to various measures of literacy. The holistic scores correlated to the holistic scores we gave the CAT4s ($r=.425$). Both holistic and rubric portfolio scores for SRL correlated to the pre-CAT4 government scores ($r=0.465$ and $r=0.593$ respectively).

Scholarly Significance

Inter-rater reliability is adequate and the validity is somewhat supported by our preliminary results. The second year data demonstrates markedly improved implementation. Nonetheless, our findings suggest it is advisable when judging portfolios across diverse classrooms to double-code the portfolios and discuss discrepant cases. The inconsistency of work in the portfolios remains troublesome: What score does one assign a 'mixed bag' such as the portfolio? We are currently exploring whether coding only the 'presentation' space improves the validity of the portfolio scores as it may better represent students' final achievements. Less traditional means of 'standardized assessment' beg the question of how to fairly assess them. The experience of coding the CAT IV's where the task demands and time constraints were

held constant contrasted sharply to coding EPs, but the very fact that the prompts are diverse and that students choose their own unique pieces is why this type of assessment compels us.

PAPER PRESENTATION

Transformations between different forms of representations in mathematics – analyzing students' ability

Marion Geiger, Ulm University, Germany; Ulrike Stradtman, Ulm University, Germany; Markus Vogel, University of Education Heidelberg, Germany; Tina Seufert, Ulm University, Germany

In mathematics learners have to deal with different forms of representations and more over with different levels of abstraction. Hence, learners often have to transform one type of representation into another one. In our study we investigated whether students with different educational background (middle or high level school, university; $n=129$) have difficulties with transformations between different sign systems (depictive or descriptive representations) and between abstract mathematical representations and real-world representations. Moreover we analyzed whether it is especially difficult to switch from one direction to the other or vice versa and we wanted to find out which type of representation is the most difficult to produce. With a set of 19 tasks in the mathematical domain of linear functions where one representation in a specific format had to be produced based on a given one in another format we analyzed the accuracy in form and content of the produced representations. We found that learners have especially problems when they have to transform between different levels of mathematical abstraction. Transformations between different sign systems were not difficult per se but depended on the type of representation that had to be produced. Especially the production of text or formulas had been difficult. The deficits were comparable for learners with different educational background, with the exception that university students struggled most with transformations between sign systems and considerably with verbalizations or abstractions in formulas. Overall, it seems fruitful to further investigate the processes of transformation and to develop instructional means to help students.

Introduction

In mathematics different representations like graphs or formulas play an important role. The effective use of multiple representations, i.e. the construction of an integrated mental model of the representations, can lead to deeper understanding. However, this requires to understand each representation as well as to integrate them, i.e. in many cases to translate between descriptive and depictive representations. Moreover, in mathematics learners often have to switch between the abstract mathematical and the real world, for example when word problems have to be solved by using a formula or a mathematical graph. A large amount of empirical research shows that learning with multiple representations is often difficult (Ainsworth, 1999) and even leads to lower learning outcomes than learning with single representations. This could be due to problems with the integration process and especially with the transformation process. In our study we analyzed transformation processes in the domain of mathematics. The aim was to find out which transformation process is most challenging and which representation is most difficult to produce. We assumed that based on empirical findings on learning with multiple representations and a pre-study on transformations in mathematics (Seufert, Vogel & Brýnken, 2008) learners will have difficulties with both types of transformation processes.

Method

To test our hypotheses we developed 19 tasks in the mathematical domain of linear functions for all types of transformations. Learners were given for example a graph and were asked to produce the formula of the underlying linear function. Before the test started, all learners were given basic information about linear functions in order to avoid prior knowledge effects. As dependent variable we evaluated the produced representations with regard to their form (e.g. correct labeling of the coordinate system) and content accuracy (e.g. right slope of the line). In a within-subject design we analyzed whether tasks with different requirements led to different results. To allow a broader generalization of the results we analyzed students with different educational background (46 eighth-grade students from middle-level school (A), 43 ninth-grade students from higher level school (B) and 40 natural-science-students from University (C); total $n = 129$).

Results

For transformations between mathematical and real-world-model we found a main effect in both subsamples A and C and by trend for subsample B: The tasks with transformation were more difficult than tasks without. Moreover we found that the change from mathematical to real-world model was more difficult than vice versa (for all results see table 1). Looking at the tasks with transformations between descriptive and depictive representations we found that university students had more difficulties to solve tasks with such a transformation whereas school students had more difficulties with tasks without transformation. Overall, we found for all subsamples that students had more difficulties

to solve tasks with a change from depictive to descriptive representations than vice versa. The analysis for different types of representation that had to be produced revealed the most interesting result: Especially the production of texts and formulas has been difficult in contrast to graphs and tables.

Summary and Discussion

Overall, we found that especially school students had enormous problems in transforming different types of representations. For half of the tasks the probability of task solution was less than 60%. Moreover, we found almost no differences between students of different educational level. However, despite our theoretical assumptions the difficulties were not that closely related to the type of transformation. Especially transformations between different sign systems seem to challenge learners with different background in a different way. It seems more important what type of representation had to be produced. Here we found that all learners (and especially university students) struggled with the production of text and formulas, i.e. with verbalisations or abstractions. Transformations between different abstraction levels also turned out to be difficult for all learners which support other findings from maths studies (see Vogel et al., 2006). As a next step we want to develop instructional aids for transformation with a special focus on the verbalization of the meaning of different mathematical representations.

PAPER PRESENTATION

An investigation on Chinese teachers' realistic problem solving ability and beliefs

Limin Chen, Shenyang Normal University, China , China; Wim Van Dooren, K.U. Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

Fourteen word problems - half of which were problematic from a realistic point of view - were administered twice to 208 pre-service elementary school teachers from Shenyang Normal University in China. First, the teachers were asked to solve the word problems themselves, and, afterwards to evaluate different pupil answers to the same problems. The results revealed, first, that these future teachers behaved remarkably realistically not only when solving these problematic word problems themselves, but also when evaluating the pupils' answers. Second, we found a strong relationship between teachers' own problem solving performance and their evaluations of pupils' answers. We end this contribution with some theoretical, methodological and educational implications of the research.

Recent studies have provided ample evidence for a phenomenon whereby elementary school pupils, and even (pre-service) teachers, solving word problems in school, often produce answers without regard for realistic constraints (Greer, 1993; Verschaffel, De Corte & Lasure, 1994; Verschaffel, Greer, Van Dooren & Mukhopadhyay, 2009). The present study with Chinese pre-service teachers, which replicates Verschaffel, De Corte, and Borghart's study (1997), provides further insight into one of the instructional factors that are considered responsible for the development of this tendency among children, namely the teachers' own ability to solve these problems realistically and their beliefs about the role of real-world knowledge and realistic considerations in school mathematics. Because there is ample evidence that different countries are characterized by different classroom cultures and practices (Cai & Hwang, 2002), and because the teacher is a pivotal factor in the establishment of the classroom and practice, Verschaffel et al. (1997) made a strong plea for replicating their study in other countries.

In the present study, a problem solving test consisting of 14 word problems - half of which were problematic from a realistic point of view - and a corresponding problem solving questionnaire were administered to 208 pre-service elementary school teachers from Shenyang Normal University in China. The following problem is an example of such a problematic item: "John's best time to run 100 meters is 17 seconds. How long will it take him to run 1 kilometre?". A typical non-realistic answer (NA) to this item is " $17 \times 10 = 170$ seconds"; examples of realistic answers (RA) are "more than 170 seconds, because John will run slowly by slowly during running 1000 meters." or "it is impossible to give a

precise answer, because I don't know John's average velocity of running 1000 meters" (Verschaffel et al., 1997). In the problem solving test the teachers were asked to solve the word problems themselves, whereas in the problem solving questionnaire they had to evaluate different pupil answers to the same problems by giving them a 1, $\frac{1}{2}$ or 0 score. These pupil answers always included the typical NA and a typical RA (see Enclosure 1). The administration of the test and the questionnaire and the data analysis were done in the same way as in the original study of Verschaffel et al. (1997).

Compared to the student-teachers from the study of Verschaffel et al. (1997), Chinese pre-service teachers firstly behaved much more realistically while solving the problematic items themselves. Indeed, 76% of all reactions to the seven problematic items could be considered as realistic, which is considerably higher than the percentage of realistic reactions (48%) that Verschaffel et al. (1997) observed for Flemish pre-service teachers. Secondly, compared to their Belgian counterparts, Chinese pre-service teachers' evaluations of pupils' realistic and non-realistic reactions to the same problematic items also revealed a more positive attitude toward pupils' reactions that involved realistic considerations. Specifically, in 70% of cases did the RA receive a score of 1 (versus only 47% in the Flemish study); 11% of the RAs received a $\frac{1}{2}$ -score and in only 19% of the cases the RA was scored with a 0. On the other hand, the NA was scored with a 1 in only 23% of the cases (versus 56% in the Flemish study), whereas 55% and 22% of the NAs received respectively a $\frac{1}{2}$ - and 0-score. Thirdly, there was a rather strong relationship between teachers' own performance on the problem solving tests and their evaluations of pupils' realistic and contextually inappropriate reactions in the questionnaires. Most participants who answered a problematic item in a non-realistic manner themselves tended to score the non-realistic pupil answer with 1 and the realistic answer with 0 in the problem solving questionnaire; and those who answered a problematic item in a realistic manner themselves had a very strong tendency to score the realistic answer with 1 and the non-realistic answer with $\frac{1}{2}$ or 0 in the problem solving questionnaire.

We end this contribution with some theoretical, methodological, and educational considerations.

First, although this study shows a strong link between how the pre-service teachers solve word problems themselves and how they evaluate pupils' answers, it reveals also how various kinds of pedagogical content knowledge and beliefs interfere in this relationship and make this link less simple and straightforward than one might expect at first sight. In this respect, we emphasize that we did not assess (pre-service) teacher's actual evaluation behaviour in a real classroom, but only a kind of simulation of this important part of their teaching task. It would, therefore, be interesting to investigate how (pre-service) teachers actually react to different kinds of pupil responses in the dynamic complexity of a real classroom situation.

Second, Chinese pre-service teachers behaved much more realistically towards problematic word problems than their Flemish counterparts. At the same time we know, from previous research (Verschaffel, Greer & De Corte, 2000; Verschaffel, Greer, Van Dooren & Mukhopadhyay; 2009) that Chinese elementary school pupils do not behave more realistically to the same problems than their Western peers. This raises the intriguing question for further research of how to explain the weak results of Chinese pupils, if they can't be explained by teachers' weak realistic problem solving capacities and beliefs. Alternative explanations referring to the broader (mathematics) educational contextual constraints wherein these teachers have to operate (Cai & Nie, 2007), might then help to explain what emerges from these contrastive data.

Finally, even though the Chinese (pre-service) teachers demonstrated a relatively strong tendency towards realistic problem solving, still a quarter of all problematic items was solved non-realistically during the problem solving test. So, it remains recommendable to further stimulate and help Chinese (pre-service-) teachers to construct the proper concepts, skills, and beliefs that are needed for realistic problem solving in the teacher training program.

PAPER PRESENTATION

Students' reported reasons for their representational choices in linear-function problems

Ana Acevedo Nistal, K.U.Leuven, Belgium; Eva Ceulemans, K. U. Leuven, Belgium ; Wim Van Dooren, K.U. Leuven, Belgium; Lieven Verschaffel, Katholieke Universiteit Leuven, Belgium

This study aimed at obtaining a comprehensive picture of students' justifications for their representational choices when solving linear-function problems. Thirty-six students aged 14-17 took a computerised test in which they solved twelve linear-function problems by selecting a table, a graph, or a formula to solve each problem. Then, each student solved three more problems (parallel to those in the computerised test) during a videotaped interview in which they were asked to think aloud while problem solving, and to justify their representational choices. A cluster analysis grouped students in four distinct clusters with regards to their representational choices in the computerised test: formula-only, table-only, graph + formula, and graph + table. The interview protocols showed that students of all four

groups tended to base their choices on subject-related reasons (e.g. their perceived fluency with the different representations) and context-related reasons (e.g. their mathematics teacher focusing on the use of formulae for problem solving). Students did not often report specific task characteristics as influencing their choices, which suggests that they might have not been aware of differences between tasks and how these relate to different representations. Further research is suggested in the form of an intervention aimed at actively encouraging students to reflect on their representational choices while solving linear-function problems. Such an intervention could reveal whether active reflection on representational choice actually improves the chances of students making more appropriate representational choices.

Aims

As Diezmann and Lowrie (2009) explain, the twenty-first century citizen is exposed to diverse quantitative data (stock-market prices, government budgets, etc) presented in various representational formats (tables, graphs, etc). Not surprisingly, teaching students to interact with external representations is an important goal in today's mathematics education. In a previous study (Acevedo Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2010) we adopted the choice/no-choice method (Siegler & Lemaire, 1997) to evaluate students' representational choices while solving linear-function problems. While this study provided valuable information concerning the impact of representational choices on problem-solving performance, students' reasons to make specific choices remained unclear. This study aimed at obtaining a more comprehensive picture of the cognitive processes underlying representation selection:

Which reasons do students report to justify their representational choices?

Based on a literature review of previous work on representational choice (Acevedo Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2009), we expected students' reasons to relate to three categories: task (e.g. choosing a particular representation because of characteristics of the to-be-solved problem), subject (e.g. avoiding a representation because of one's low fluency with it), and context (e.g. selecting a representation because the mathematics teacher uses this representation the most).

Methodology

Thirty-six students aged 14-17 took a computerised pretest. They solved twelve linear-function problems about the concepts of slope, y-intercept, and intersection between two functions. To solve each problem, students had to choose a table, a graph, or a formula. Three days later, students were interviewed. During the interview, which was videotaped, they solved three problems parallel to those in the pretest while thinking aloud. For each problem, the student selected his preferred representation, justified his choice, and finally solved the problem with that representation. This procedure was repeated two more times until the student had solved the problem with all three representations

Findings

A cluster analysis of the pretest data revealed four distinct clusters with regards to representational choice: formula-only (n=3), table-only (n=16), graph +formula (n=9), and graph+table (n=8).

Formula-only cluster(n=3)These students' main reason to choose the formula was subject-related: They believed they were proficient with it. However, in reality only two students were actually proficient (75% accuracy with the formula in the pretest), but not the third (25% accuracy). Surprisingly, this group did not show a preference for the formula in the interview despite doing so in the pretest. One student argued that tables and graphs are more appropriate to explain how to solve a problem (i.e. in the interview), whereas the formula is more appropriate to actually solve the problem (i.e. in the pretest). Clearly, her choices were influenced by context-related reasons.

Table-only cluster(n=16)Subject-related reasons were also the most popular here (n=10), e.g. "I understand tables very well, and that's why I trust them the most". This group displayed 80% accuracy with the table in the pretest, so their perception about their table fluency was accurate. Only four students reported task-related reasons to choose the table – in an intercept problem, three mentioned that they expected to find a 0-point in the table; in a slope problem, one student remarked that he could easily find the increment per unit in the y-column.

Graph+formula cluster(n=9)Three students reported task-related reasons to justify their choices – for intersection problems they preferred the formula, for the other problems the graph. Two students reported subject-related reasons (e.g. "I prefer to work with formulae in general"), one by context-related reasons (e.g. "In class we use the formula much more often than the other two"), and three by a combination of subject and context-related reasons (e.g. "We work more often with formulae. I get to practice more, that's why I am better at them").

Graph+table cluster(n=8)Two students referred to task-related reasons to justify their choices (e.g. "The problem asks you about the relationship between two variables, that's why I chose the table"). The remaining six students invariably referred to subject-related reasons to explain their preference for graphs and tables (e.g. "I am good at using graphs, that's why I chose it"). None of the students in this cluster mentioned context-related reasons.

Theoretical and educational significance

Adopting a combination of quantitative and qualitative methods to study problem solving with external representations allowed us to explore the reasons that (reportedly) underlie students' choices. This study revealed that students do not always have a realistic conception of their own fluency with representations, which may lead them to misjudge their chances of solving a problem with a specific representation. Students do not often report task characteristics as influencing their choices, and this could actually mean (at least in some cases) that they are not aware of differences between tasks and how these relate to different representations. This could be partially due to the fact that, in Spain, mathematics instruction traditionally focuses on using formulae for problem solving, regardless of problem type. Further research could be conducted in the form of an intervention where students could be encouraged to reflect on their representational choices, the purpose being to evaluate whether such reflection improves students' chances of making more appropriate representational choices in subsequent problems.

PAPER PRESENTATION

Low attaining children's understanding and use of the additive composition principle

Chronoula Voutsina, University of Southampton, United Kingdom

The paper presents findings from a project which aimed at exploring low attaining children's sensitivity to problem relationships based on additive composition and possible variations in children's understanding and capability to use such relations in problem solving. Fifteen 6-7 year-old children solved conceptually related and unrelated addition problems in individual sessions. All problems involved single-digit additions up to 20 with two or three addends ranging between 1 and 9. Conceptual relations between problems were constructed to reflect aspects of the principle of additive composition. Children's understanding of additive composition relations was explored by analysing children's strategy use and explanations of the equality between conceptually related problems. The findings indicate high within-group variation in children's capability to recognise and use numerical relations between problems. Children who used mainly basic calculation procedures were able to explain retrospectively why two problems had the same answer by recognising the numerical, part-whole relations between problems. Prompting children to use a previously solved problem did not have a considerable effect in children's noticing of the numerical relations but the requirement to explain the problem equality evoked greater sensitivity to additive composition relations. The findings highlight the need for pedagogical approaches that enable low attaining children to operationalise their capabilities into their learning.

Background

Understanding of the additive composition principle, that is, knowing that numbers can be decomposed in different parts which can then be recombined in different ways in order to create the whole is fundamentally linked to children's mathematical achievement (Cowan 2003). Canobi et al. (1998) found that children's ability to spontaneously recognise additive composition relationships when solving conceptually-linked addition problems is useful in defining conceptual understanding. The researchers concluded that for the children who failed to recognise problem relationships, "insensitivity to relationships may lead to a reliance on inefficient problem-solving strategies that, in turn, may restrict their opportunities for development in conceptual understanding" (p. 890). This paper reports

findings from a project that sought to answer the research question: to what extent the reported insensitivity to additive composition relations is a unifying characteristic of children who typically use inefficient strategies?

Methods

The current pilot study aimed at examining low attaining children's sensitivity to problem relationships based on additive composition. The participants were fifteen 6-7 year-old children (8 girls, 7 boys) attending Year 2 classes in four inner-city schools in southern England. Near the end of Year 2 the children had been assessed by their teachers as working within the National Curriculum sub level 1c which is below the average expectation (The National Curriculum 1999).

In individual video-recorded sessions children solved twelve pairs of conceptually-linked addition problems and six pairs of unrelated problems. All problems involved single-digit additions up to 20 with two or three addends between 1 and 9. For example, in pairs of related problems $8+5=$ was followed by $8+4+1=$; and $5+2+4=$ was followed by $7+4=$. Each problem was presented on a 5cm'20cm laminated card. Once solved, the first problem remained visible while the second problem was presented. Canobi et al.'s (1998) problem solving and judgement tasks were adapted to develop a single task in which children were prompted to notice and use numerical relations not only through the problem structures but also through the interviewer's instructions. The children were asked consistently to look at the previously solved problem and think how they could use it to solve the current problem.

Children's counting and non-counting strategies were classified following Geary's (2003) typology of addition strategies. We ascribed the 'equality' approach to children who reported that they solved a problem by noticing the numerical relations and equality between that and a previously solved related problem. $5+6+1=$ was presented to Kyle after solving $5+7=$. He said: " It's the same, 12, ?cause that's 5 and 5 (shows 5 as first and second addend in both problems) and 6 add 1 I know is 7 and that's 7" (shows 7 in preceding problem). Report of the 'equality' approach was used as a measure of conceptual understanding. When, despite being prompted, children did not refer to a related problem but used other methods (e.g. counting), the researcher asked them to explain why they thought the two problems had the same answer. Children's ability to explain the equality between problems by referring to the numerical relations was used as a second measure of understanding additive composition. Children's use of the 'equality' approach in related problems and explanations of the equality between problems are reported below.

Outcomes

Despite the prompts, children reported the use of the 'equality' approach in only 19.4% of their answers. Its emergence indicates the ability of some of the children to use, when prompted, a concept-based approach.

Figure 1 (appendix). Percentages showing individual children's use of 'equality' as solving approach and explanations for the equality between problems when 'equality' had not been used.

The graph shows that the majority of children were able to recognise additive composition relations when explaining the equality between problems, even when they had not used these. Mina solved $5+7=$, using counting-on with fingers from 5. When presented with the related problem $5+6+1=$, she used counting-on from 5 again. When asked to explain why the two problems had the same answer she explained: "You've got 5 and 7 (shows the first sum) and you've got 5 there again (shows the 5 in the $5+6+1$) and 6 and 1, Oh! that's... 6 add 1 is 7, isn't it? It is 5 add 7 (shows the first sum) and that's 5 add 7 if you stick them together! (shows the 6 and 1 in the second sum)". Our data indicate high within-group variation in children's capability to recognise and use numerical relations between problems. Children who used mainly basic calculation procedures were able to explain retrospectively why two problems had the same answer by recognising the part-whole relations between problems.

Discussion

Within the context of the same task, prompting children to use a previously solved problem did not have a considerable effect in children's noticing of the numerical relations. Conversely, the requirement to explain the problem equality seemed to evoke greater sensitivity to additive composition relations. Sophian (1997) discussed differences between competence and performance on the basis of children's cognitive goals and the changing nature of these as children grow older. Children's changing sensitivity to additive composition relations could perhaps be explained on the basis of triggering a change or development of goals. On these grounds, differences in cognitive goals could explain performance differences within the same-age group and not only between younger and older children. Given the dynamic relation between conceptual knowledge and goal-based activity (Sophian, 1997), future research needs to explore more widely the aforementioned suggestion and the extent to which educational activities can shape low attaining children's goals to support their learning.

PAPER PRESENTATION

Changing the way students interpret the phenomenal sign of algebraic expressions

Konstantinos P. Christou, University of Crete, Greece; Stella Vosniadou, National and Kapodistrian University of Athens, Greece

The purpose of the present study was to investigate the effect of a short intervention in the form of direct instruction on the remediation of the phenomenal sign bias in algebra. The phenomenal sign bias is students' tendency to interpret the phenomenal sign of algebraic expressions to be the actual sign of the numbers they can only represent (i.e., $2x+1$ stand only for positive numbers, $-2x-1$ stand only for negative numbers). We interpret this phenomenon to be a by-product of students' tendency to interpret literal symbols to stand for natural numbers only (Christou & Vosniadou, in press). In the present study a short instructional intervention was based on the principles of direct instruction and also using the refutational argumentation methodology. Refutational argumentation consists of directly stating students' erroneous conceptions and then refuting them, using specific examples and counter examples. The participants were 20 10th graders. Students' phenomenal sign bias errors were measured before, immediately after the intervention and one month later, using mathematical tasks from the domain of algebraic inequalities, square root functions, and absolute values. The results showed that the students performed significantly better in the immediate post-test compared to the pre-test, but not in a delayed test conducted after a month. In addition, the high achieving students profited more by the intervention than the low achievers. The value of short term direct instruction for producing conceptual change learning will be discussed.

Purpose and theoretical considerations

The aim of the present study was to investigate the effect of a direct, refutational type, instructional intervention on the remediation of the phenomenal sign bias in the way students interpret algebraic expressions, and to test of the robustness of this bias. The phenomenal sign bias lies in students' tendency to interpret the phenomenal sign of an algebraic expression not as a superficial characteristic of its form but as the actual sign of the numbers that the expression represents. In other words, students tend to think of expressions such as $2x$ to stand for positive numbers only, and expressions such as $-2x$ to stand for negative numbers only.

Previous research has shown that from an early age students have organized their conceptions about number into a framework theory of number which resembles the mathematical concept of natural number (Ni & Zhou, 2005; Vosniadou, Vamvakoussi, & Skopeliti, 2008). Students' framework theory of number affects their beliefs about what numbers are and how they behave (Vosniadou, et al., 2008). Previous studies have showed that students' initial framework of number affects the way they interpret the use of literal symbols to stand for variables in algebra. More specifically, the students tend to think of literal symbols to stand for natural numbers as opposed to any real number (Christou & Vosniadou, in press). As a result, they interpreted the algebraic expression $4g$ to stand for natural numbers multiplicatives of 4, or expressions such as a/b to stand only for positive fractions. Recent studies also showed a tendency on the part of the students to think of positive-like algebraic expressions to stand for positive numbers only and negative-like expressions to stand for negative numbers only, namely the phenomenal sign bias. We have argued that students' phenomenal sign bias is probably related to students' tendency to interpret literal symbols to stand for natural numbers only (Christou & Vosniadou, in press).

If the phenomenal sign is a byproduct of the whole number bias, then it would be difficult for students to overcome, because, as other studies have shown, removing the whole number bias is a difficult and time consuming process (Ni & Zhou, 2005). However, it could also be argued that the phenomenal sign bias is not a deep seated bias but, rather,

that it is caused by an oversight on the part of the students, a rather casual error. If this bias is a casual oversight, then a short, direct-type of instruction intervention should be adequate to remedy it.

A direct instruction/refutational lecture intervention

The direct instruction was organized around the refutational argumentation methodology. This methodology tries to alert students about their inadequate existing ideas, it argues against them, and it proposes another perspective which is presented as more adequate. Research has shown that such methodologies are effective on increasing students' metaconceptual awareness which supports learning that requires the revision of inadequate initial conceptions (Palmer, 2003). The teaching intervention had the form of a lecture which was designed using the main principles of direct instruction. More specifically, it used clear definitions of the concepts, examples and counter examples to denote the phenomenal and the actual sign of the expressions, and also specific strategies were suggested such as to try with as many different kinds of numbers as possible in order to check the sign of an expression.

Method

The participants were 20 10th grade students. The phenomenal sign bias was measured with three multiple choice questionnaires: a pre-test before the intervention, a post-test immediately after the intervention, and a delayed post-test one month after the intervention. The questionnaires included tasks from the domain of square root functions, algebraic inequalities and absolute values. The direct instruction refutational lecture took place in students' classroom by one of the researchers and lasted about 20'.

Results and Discussion

The results showed significant differences between the pretest and the immediate posttest. The students made significantly fewer mistakes due to the phenomenal sign bias in the posttest (Wilcoxon Signed Ranks Test: $Z=2.074$, p Wilcoxon Signed Ranks Test: $Z=2.310$, p , but their performing rates were maintained high in the delayed test. Overall, the results of the present study support the view that the phenomenal sign bias is robust, is based on the more general whole number bias, and that it is not easy for students to overcome. Teaching interventions like the one we used can be helpful on the remediation of such biases. However, for more permanent results, that would affect also the low achievers, instructional interventions should take a more long term perspective and try to enrich students' concept of number from the narrow focus on whole numbers to rational and real numbers.

PAPER PRESENTATION

A new one-year intervention program for 4-year-old children with low numeracy: first results

Pekka Rasanen, Niilo Maki Institute, Finland ; Minna M Hannula-Sormunen, University of Turku, Finland;
Aino Mattinen, Niilo Maki Institute, Finland; Erno Lehtinen, University of Turku, Finland

There are still very few evidence-based remedial programs for children at the age of 3 to 5 years, which would include one of the key components in thinking and cognition: numeracy.

"The Teddy Bear Math" was designed to be an easily implementable once a week group program with the aim to improve children's numerical skills and executive functioning. The program contains weekly small group session, bridging to daily life, as well as materials for co-operation with parents.

A four months pilot study with 24 children with mild cognitive delay was conducted. Children were divided into two subgroups: 14 (mean age 4 years) started from the first phase of the program and 10 (mean age 4.7 years) from the phase two of the program. Children were divided into these groups based on the pre test results. A post-test and a delayed post-test (5 months) were used. The effectiveness of the intervention was analysed with three summary

scores: (1) numerical skills and (2) executive functioning (working memory and comprehension) as target skills, and (3) Phonological-linguistic skills as a control measure. There was a significant improvement in numerical skills and executive functioning (p

Aims

The aim of this study was to get information about specific effects of a new intervention program designed to improve 4 to 5 year old children's numerical and cognitive skills. "The Teddy Bear Math" (TBM) was designed to be an easily implementable once a week group program with the aim to improve children's numerical skills and executive functioning. The program contains a small group session, bridging to daily life, as well as materials for co-operation with parents.

The theoretical background of the program rests on the socio-cultural views of teaching-learning interaction within the proximal zone of development (e.g. Rogoff, 1990; Vygotsky, 1978). The structure of the program and its activities remind those found in several enrichment programs (e.g. Ashman & Conway, 1989; Feuerstein, Rand, Hoffman & Miller, 1980; Greenberg, 2000; Haywood, Brooks & Burns, 1992). The main difference is that in the TBM training of more general learning prerequisites is done in the context of early number skills (Mattinen, Räsänen, Hannula & Lehtinen, 2008).

Methodology

In this first (pilot) study only an experimental group was used. To analyse the immediate intervention effects, improvement from pre-test to post-test (intervention) was compared to that from post-test to delayed post-test (no-intervention). The logic of this kind of a comparison comes from the findings that for children with cognitive difficulties long-lasting intervention effects would require maintenance and without this a decline in improvement can be found (Ramey & Ramey, 1998). Therefore we expected a larger improvement effect during the intervention than in an as long time period after it without any maintenance activities.

Participants

The day-care personnel who were given a short checklist type of cognitive skills analysis did the initial selection. After this a thorough assessment was done and 24 children were selected to the study: 14 of them (mean age 4.0 years) started from the phase 1 of the TBM program and 10 (mean age 4.7 years) from the phase 2. Both phases last 5 months. The children were divided into groups of 4 and trained assistants from their own day-care centres conducted the intervention sessions.

Assessments

Three scores were used to analyse the intervention effects. Numerical skills and executive functions were the target variables and phonological-linguistic skills were a control variable, i.e. area where intervention effect was not expected. The tasks and their reliability are presented in Table 1.

The numerical tasks were experimental, all other cognitive measures were from the NEPSY: A Developmental Neuropsychological Assessment battery (Korkman, Kirk, & Kemp, 2008) and were presented in a standard fashion.

Findings

First we standardised all scores, calculated summary scores and from those we calculated standardised gain scores (later assessment – previous assessment / standard deviation of the first assessment). This score corresponds to Cohen d effect size. Due to a small sample size we used 99% as a criteria for a significant result.

Children's development both during the intervention and after it differed from 0 ($p F(4,19)=1.559, p = .226$) or after it ($F(4,19)=.820, p = .528$). Therefore the subgroups were combined in the last analysis.

We analysed whether there was more improvement during the intervention than after it without intervention. As can be seen from Figure 1. there was a large improvement in numerical skills and executive functioning ($d > .50$) during the intervention but only a small development in phonological-linguistic skills. The improvement in the first two cognitive skill areas was significantly larger during intervention than after it (p

Educational significance

The TBM program is the first attempt to develop remedial numeracy program for children with developmental cognitive delays. The first study on the effectiveness of the TBM program to improve numerical and more general cognitive skills gave promising results. However there would be many things that would increase the effectiveness of the program.

First, the intensity of the remedial program is critical factor. The TBM program has only one session a week. It might produce even better results if it were more intensive. However, this feature is a compromise between effectiveness and usability. Too intensive programs cannot be taken as a standard part of day-care activities.

Secondly, bridging the intervention into everyday life is a critical factor. The TBM program contains activities outside the weekly session. Likewise the program contains weekly letters to be sent home to activate parents to interact with their children on similar topics. Additional questionnaire data showed that only a small proportion of parents took constantly those ideas into reality. This is critical issue to be developed.

Third, more research is needed to find out the how the activities should be designed. The biggest problem in small group activities is to get everyone equally attentive and participatory. Analysing the videotaped sessions from this study helped us to modify many activities to the final version of the program, but training the day-care personnel is as critical.

Finally, controlled studies with larger groups are needed to confirm the effectiveness. Currently we are conducting a broader study with mathematical age and chronological age comparison groups with a control intervention. The early results of this broader study will also be shortly introduced in the presentation.

PAPER PRESENTATION

Factors influencing the acquisition of science knowledge in grade 4

Erzsebet Korom, University of Szeged, Hungary; Erzsebet Antal, University of Szeged, Hungary

This paper presents initial findings from a longitudinal study on a nationally representative sample. Launched in 2003, the study follows students through their time in public education (grades 1-12), collecting data on their development annually and in important areas. The first assessment of science knowledge took place in May 2007, when students arrived at the end of the foundation period of their education in grade 4. The sample included 4,428 students (from 113 schools and 220 classes). The science test targeted one element of science knowledge, namely, declarative knowledge, by focusing on the developmental level of the most important basic concepts. Analyses were performed to establish the extent to which cognitive and non-cognitive variables affect, determine, perhaps define later performance on the science test. No gender-related differences were found in performances. However, between-school differences were significant. From among the basic skills assessed in grade 1, elementary arithmetic proved to be the major predictor of grade 4 science acquisition levels. The greatest contributors to explaining the variance of performance on the science knowledge test were elementary arithmetic (15.6%) and inductive reasoning (14.2%), but considerable effects could be attributed to reading comprehension (11.9%) and mathematical reasoning as well (8.4%). These findings highlight the importance of thinking skills in the acquisition of declarative knowledge.

Summary

A fundamental objective in science teaching is that, as a result, students have a well organised knowledge, a scientifically based view of the world. One condition for this to happen is that they acquire basic scientific concepts, facts, relationships. A deeper understanding of the factors influencing conceptual development may contribute to curricular and methodological advancement. This paper presents initial findings from a longitudinal study, in which basic science knowledge is regularly assessed, and relationships are investigated between students' performance and other related information (e.g. their basic skills, reading, mathematical reasoning, inductive reasoning, academic attitudes, academic achievement).

Theoretical background

Research on concept formation and the acquisition of concepts is an important area where science education and cognitive developmental psychology overlap. A great body of data have been gathered on the processes of conceptual development and conceptual change in early childhood, their domain-specific characteristics, as well as the cognitive, affective and social factors that influence concept formation. The findings show a connection between the developmental level of thinking abilities and content/conceptual knowledge. There is also evidence that in conceptual development, in addition to cognitive factors, affective ones (mastery motivation, academic self-concept, and self-efficacy) also play an important role (Pintrich, Marx and Boyle, 1993). Students' performances are fundamentally affected by their knowledge, abilities, attitudes and the experiences, genetic inheritance (White, 1988; Biemans, Deel and Simons, 2001). Studies on the acquisition of science knowledge have mostly been cross sectional examinations, targeting different age groups and subject areas. Recently, longitudinal studies have been receiving more attention, because they offer the opportunity to follow students' development and also to diagnose problems in comprehension,

to predict difficulties in knowledge acquisition, and to analyse the effect of individual factors and the changes of influences in multifactor systems.

Objectives and research questions

This paper presents initial findings from a longitudinal study on a nationally representative sample. Launched in 2003, the study follows students through their time in public education (grades 1-12), collecting data on their development annually and in important areas. The first assessment of science knowledge took place in May 2007, when students arrived at the end of the foundation period of their education in grade 4. The sample included 4,428 students (from 113 schools and 220 classes). The science test targeted one element of science knowledge, namely, declarative knowledge, by focusing on the developmental level of the most important basic concepts. The test consists of two parts (biology and physics-chemistry) and involves both closed and open ended questions. The development of basic science concepts is measured biennially with expanding test-series.

Other test results, besides those of this knowledge test, are also available with this sample. At the beginning of the longitudinal project, in grade 1, the level of basic skill development was measured with the help of a diagnostic test system, including measures of social skills, writing movement coordination, relation vocabulary and deduction. Tests of mathematical thinking, knowledge in mathematics, reading comprehension and inductive thinking have been administered to the sample several times, beginning in grade 2. The test of knowledge in mathematics is adjusted to the subject-matter and the test of mathematical thinking primarily investigated proportional thinking. The test of reading comprehension measured information search and interpretation in continuous and discontinuous texts. The test of inductive reasoning contained subtests with number analogies, word analogies and sequences. In addition to the tests, background data was also collected on parents' qualification, sociocultural background, attitudes to school and school subjects and school achievement.

It was hypothesized that (1) no gender-related differences can be detected in the development of basic science concepts, (2) significant between-school differences can be found, (3) the level of basic science concept development is more closely related to other investigated cognitive factors (mathematical thinking, inductive thinking, text comprehension) than to the level of parents' qualification and (4) subtests of cognitive skills have different correlations with the results of the science test.

Results

The science test proved to be reliable (Cronbach's α : .94). The mean achievements on the test were satisfactory ($x=46.8\%$, $sd=18.7\%$), but the results of the two subtests were significantly different (physics-chemistry: $x=34.6\%$, $sd=18.8\%$; biology: $x=52.9\%$, $sd=20.7\%$). The comprehension of biology concepts were less difficult to the students. The analysis of conceptual development was presented in the previous EARLI conference, therefore this presentation concentrates on its relations with other variables. The findings supported our hypotheses: no gender-related differences were detected, but significant between-school differences were found. The mean achievements of schools covered a broad interval. The best and worst achieving schools reflected a difference of two standard deviations. Weak, yet still significant correlation was found with parents' qualification ($r=.24$) and medially significant correlations with level of basic skill development (writing movement coordination $r=.21$, relation vocabulary $r=.31$, experimental deduction $r=.33$, elementary arithmetic $r=.39$, sociality $r=.36$). Elementary arithmetic was the one of all the basic skills measured in grade 1 that prognosticated the level of science knowledge the most appropriately. Also, medially significant correlations were found with mathematics tests administered in grade 2 and 4 ($r=.38$, $r=.63$) and with mathematical thinking measured in grade 3 ($r=.55$). From all the tasks of text comprehension, science knowledge correlated most strongly with discontinuous text comprehension (poster, time-table) and with the operation of information interpretation. The degree of correlation was similar in all three cases of text comprehension measurements (in grade 2, 3 and 4). The closest connection was detected in case of the word analogies subtest in inductive reasoning ($r=.52$).

The greatest contributors to explaining the variance of performance on the science knowledge test were elementary arithmetic (15.6%) and inductive reasoning (14.2%), but considerable effects could be attributed to reading comprehension (11.9%) and mathematical reasoning as well (8.4%).

These findings highlight the importance and prognostic force of thinking skills in the acquisition of declarative knowledge. The data gained from further measurements might make it possible to observe the changes of influencing factors as well.

PAPER PRESENTATION

DYAD-COMMUNICATION MODEL FOR REPRESENTING PARENT & CHILD INTERACTIONS

Orit Hetzroni, University of Haifa, Israel; Adi Neeman, University of Haifa, Israel

Aim:

The first interaction of a newborn is usually with the parents. Through this significant bond, the child practices interactions, which are the first building blocks in the development of communication and social skills (Harrist & Waugh, 2002; Bowlby, 1969). The purpose of this study was to investigate a proposed dyad-communication model designed to represent parent-child interactions, and compare between dyads of children with and without communication difficulties and their parents using representations based on a proposed model

Method:

5 parents of toddlers with communication difficulties and 5 parents of infants without communication difficulties were selected for the study. All intelligible communication behaviors produced by parent and toddlers were transcribed from videotaped sessions. Ten sessions were videotaped to record communication dyads between parent and child at their home environment. Video sessions were analyzed to assess dyads and to determine the efficiency of the model

Results:

Results demonstrate a significant difference in the observable pattern of dyadic interactions between parents and children with and without communication disorders, in synchrony and structure

Conclusion:

Understanding the uniqueness of the dyad between a parent and a toddler with communication disorders could lead to the development of suitable interventions in order to empower the dyad. Presenting the dyads in a model could enhance understanding of such communication and increase development of intervention processes

Introduction

The first interaction of a typically developing newborn is usually with parents. Through this significant bond, the baby practices interactions, which are the first building blocks in the development of communication and social skills (Harrist & Waugh, 2002). These significant bonds, called Dyads, are defined as a mutual relationship that is usually based on verbal communication (Fonagy, Gergely & Target, 2007). Dyads are typically represented in models describing behavior and affect. The majority of these models are derivatives of studies based on typically developing children. Unlike typically developing children, these individuals have great difficulties understanding and producing language and communication, which influence their abilities to interact and express needs. Inability to experience vocal interaction affects opportunities to practice language and develop communication skills. Infants and toddlers that do not produce sound, engage in less significant interactions with the environment (Downing, 1999). Such limited interactions present fewer opportunities for feedback which may gradually decrease parental interactions (Danon-Boileau, 2006). As a result, receptive language skills are in danger as infants and toddlers engage less in communicative acts and decrease practicing their listening, which in turn reduces understanding of their needs (Mercer-Young, & Hauser-Cran, 2006). Such scenarios portray inefficient communication and restrictions that evolve into limited parent-child dyads. Communication is the basis of any relationship; the child begins to understand the world while developing communication skills, integrating in social acts and manipulating the environment. These experiences assist the child's development and dyad building with parents (Gowlett, 1994). It is strenuous and often unfeasible to attain a good dyad when one of the partners has difficulties in conveying messages. Poor dyads between infants and parents can delay development of emotional, psychological, and cognitive aspects later in life. (Brazelton & Cramer, 1990). The purpose of this study was to investigate a proposed dyad-communication model designed to represent parent-child interactions, and compare between dyads of children with and without communication difficulties and their parents using representations based on the model.

Method

Ten parents of toddlers with and without communication difficulties were selected for the study. Toddlers ranged from 18 to 30 months, all diagnosed or suspected of significant language difficulties and a parent report indicating

difficulties in understanding their toddler. Infants ranged from 6-12 months with no apparent disabilities. All intelligible communication behaviors produced by parents and toddlers were transcribed from videotaped sessions using a software program created for this study that for recording continuity, tempo, and direction. Ten sessions were videotaped to record communication dyads between parent and child at their home environment. Sessions included free-play and pre-set sessions including games, feeding, and diaper change. Parents were encouraged to act freely with their child using naturally occurring activities. Video sessions were analyzed to assess dyads and to determine the efficiency of the model. Both populations were compared using the model to determine different patterns of communication. Two independent observers coded 20% of all video sessions. Reliability was established based on 90% accuracy level using inter-observer agreement.

Results

Results demonstrate a significant difference in the observable pattern of dyadic interactions between parents and children, with and without communication difficulties, both in synchrony and structure. Infants without communication difficulties had a similar number of communicative behaviors, initiations and responses as parents, including gestures, eye gaze, and voice acts. Many attempts were made by both communication partners, and most of them were acknowledged. All behaviors of the infants were presented in the model. More than 50% of communicational attempts of the infants were recognized by their parent and vice versa. Results demonstrate stability in Dyad continuity; a tempo of an average of 20 utterances responses per minute, and a unified form in the direction of the utterances. Interactions between toddlers with communication difficulties and parents revealed few interactions with a very limited range of behaviors, most of which were demonstrated by the parent. There were many gaps and misinterpretations of the communicative acts. All data were recorded and presented in the model. Results revealed diversity between dyads regarding the aspects of continuity, tempo and direction of the utterance. Dyads between toddlers with communication difficulties and their parents presented a slow rate of communicative behaviors and fewer occurrences of exchanges. Less than 50% of the communicative attempts presented by the toddler were recognized by the parent and vice versa. Continuity was poor, there was an average tempo of five utterances per minute, and the direction of the utterances between the parent and toddler and vice versa often had a non-unified form. When comparing between dyads, the main differences lay in the synchrony and structure with a significant difference in the dyad density considering continuity, tempo and direction of utterance transfer.

Discussion

There are a limited number of studies investigating communication as a dyad between a parent and an infant or a toddler with communication difficulties (e.g., Mercer-Young, & Hauser-Cran, 2006). The goal was to represent both dyads in the dyad communication model for obtaining a better understanding of the differences between the dyads. The current study revealed that there is a significant difference between dyads of parents and children with and without communication difficulties as represented in the model. Results demonstrate that infants without communication difficulties have a general smooth flow (Harrist & Waugh, 2002), while toddlers with communication difficulties presented dyads that were characterized with a disjointed style (Harrist & Waugh, 2002). Understanding the uniqueness of the dyad between a parent and a child with communication difficulties could lead to the development of suitable interventions in order to empower the dyad. Presenting the dyads in a model could enhance understanding of such communication and increase development of intervention processes. This presentation will address the theoretical and empirical data, and present the proposed dyad communication model.

PAPER PRESENTATION

Supporting students' strategy development for solving basic chemistry problems

Sascha Bernholt, IPN Leibniz-Institute for Science Education, Germany; Andrea Anschuetz, Universitat Oldenburg, Germany

Scientists use a precise language and domain-specific concepts and terms to grasp their ideas, share their thoughts, and solve problems. In addition, prototypical symbolic systems as chemical formulae are crucial for chemists, but also one of the most difficult and unpopular topics in chemistry education. Research indicates that novices and experts apply different strategies when interpreting chemical formulae.

In order to develop successful didactical approaches, more data and results about learning strategies and difficulties are required. A computer-based learning environment was developed to answer the questions, how students' strategies evolve over time and how different supporting tools can facilitate the formation or adjustment of strategies. Students (aged 10 to 13 years) responded to tasks that required the matching of formulae with their respective names and appropriate particle models (N=418). While working on the tasks, they had the chance to use different supporting tools. Students' performance in the learning environment was analyzed based on detailed logfiles. Additionally, students' strategies were extracted based on open-ended questions and interviews.

The results show that the quality of students' strategies increased slightly, but significantly over the course of the learning environment. The use of supporting tools increased answer probabilities, but learning gains are better predicted by strategy quality. Separate path analysis were conducted to investigate the contribution of the different supporting tools to students' development of strategies.

Theoretical background

Scientists use a precise language and domain-specific concepts and terms to grasp their ideas, share their thoughts, and solve problems (Krajcik & Sutherland, 2010). As scientific and everyday language partly interfere with each other, students often have difficulties in developing, applying, and interpreting specific aspects of scientific language. In addition, prototypical symbolic systems as chemical formulae are crucial for chemists, but also one of the most difficult and unpopular topics in chemistry education for students in school and even freshman students, as numerous studies revealed (Schmidt, 1997). In this particular case, problems are mainly referred back to students' difficulties in connecting different levels of representations (macroscopic, submicroscopic, symbolic/mathematical). However, these problems do not only pertain to the use of chemical formulae but to a large array of topics and concepts across the science domains (DeJong & Taber, 2007).

Research indicates that novices and experts apply different strategies when solving science problems (Williams & Noyes, 2007). Accordingly, strategy use is a major predictor for achievement in scientific problem solving situations (Taasobshirazi & Glynn, 2009). Different approaches, among these the use of analogies (Gentner & Kurz, 2006) or the use of worked examples (van Gog, Paas, & van Merriënboer 2004), were developed to support students' problem solving strategies.

Research method and design

In order to develop successful didactical approaches, more data and results about learning strategies and difficulties are required. Therefore, we focused at first on students in introductory chemistry courses as higher order thinking skills and complex problem solving activities require multiple strategies, leading to a large variety of individual pathways and solution methods. A computer-based learning environment was developed to answer the questions, how students' strategies evolve over time and how different supporting tools can facilitate the formation or adjustment of strategies.

Students (aged 10 to 13 years) responded to tasks which required the matching of formulae with their respective names and appropriate particle models (intervention time: 90 min; N=418). They were asked for the strategies they used to identify the underlying rules of this symbolic language after each of three difficulty levels within the learning environment (open-ended questions) and in additional interviews (N=8).

While working on the tasks, they had the chance to use different supporting tools. Scale and depth of the supporting tools increased, starting with a general hint to focus on a certain aspect or offering an analogy and ending with the proper answer including an explanation. The choice whether and which supporting tools are used was up to the students.

Students' performance in the learning environment was analyzed based on detailed logfiles (responses, use of supporting tools, reaction times, etc.). Different strategies were extracted with regard to their responses to the open-ended questions and the interviews. Additionally, the learning environment was framed by pre- and post-test to investigate students' learning gains.

Results

The results show that students without prior knowledge and training in chemistry classes are able to understand the basic characteristics of chemical formulae and simple particle models and enjoy working with them. The students expressed 25 indicators to match formula and names (partially combinations). These were categorized into six levels of strategy quality. Over the course of the learning environment, the strategy quality increased slightly, but significantly (one-way repeated-measures ANOVA, $\eta^2 = .98$, $F(1.96, 777.9) = 108.54$, $p < .001$). In addition, the quality of the applied strategy correlates with the obtained scores ($r = .22$, $p < .001$).

The assumption of increasing task complexity is confirmed by gradually declining answer probabilities. These can be raised considerably by the use of the different supporting tools. As expected, the increasing amount of information within the supporting tools (from a general hint to an explanation) resulted in increasing answer probabilities. However, the students' learning gains (standardized residuals from pre- to post-test) is not directly predicted by the general use of supporting tools but by the quality of their strategies (ANOVA, $F(5,412) = 1.64$, $p < .05$, $R^2 = .06$).

Separate path analysis were conducted to investigate the contribution of the different supporting tools to students' development of strategies and their obtained scores over the course of the learning environment. Satisfactory fit indices for the impact of the supporting tools on strategy quality and scores were revealed only for the model including "analogies" as supporting hints ($\chi^2/df = 1.52$, $p > .05$, CFI = .978, RMSEA = .34, AIC = 117,55).

The results show possible approaches to identify students' strategies when solving problems in a self-paced manner. However, further research is needed to develop descriptive and prescriptive models of student learning and their development of strategies. Further interviews accompanied by eye-tracking are currently in preparation to gain insights into students' course of action when working on formulae and submicroscopic structures. First results will be presented on the conference.

PAPER PRESENTATION

Dialogue, the social brain and creative thinking

Neil Mercer, University of Cambridge, United Kingdom; Karen Littleton, Open University, United Kingdom

Several fields of investigation, including developmental psychology, educational research and neuroscience, have begun to converge in stressing the essentially social quality of human creativity. Research has also begun to reveal the importance of certain forms of social interaction for the intellectual development of children as creative individuals. In this theoretical paper we will discuss the findings of such research for our understanding of creative processes and the role of interpersonal dialogue within them. Focusing particularly on the role of spoken language as a tool for collective and individual thinking, we will draw out implications not only for theoretical accounts of creativity, but also for educational policy and practice.

Taking a view of creativity as having a fundamentally and necessarily social basis, and in many cases being the outcome of an explicitly collaborative endeavour, this theoretical paper will offer new insights for our understanding of creative thinking and activity and how creativity can be promoted through education. It is essentially based on an extended version of sociocultural theory (the neo-Vygotskian perspective which is sometimes called 'cultural-historical activity theory'), but it also resonates with recent neuroscience research on the 'social brain' (e.g. Frith & Singer, 2008).

The paper will explore the growing body of work regarding how people act creatively together and it will draw on our own research data (and associated analyses) as part of this exploration. It will not focus solely on the processes of collective creative endeavour, but aims to reconcile them with notions of individual creativity. The suitability of sociocultural theory as a basis for understanding both individual and joint creative activity will be critically examined, by showing how such activity is predicated on the shared historical knowledge of communities and the use of language (as a cultural and psychological tool) which is used with other communicative tools for pursuing and achieving communal goals. Sociocultural theorists have argued that the relationship between social (intermental) and psychological (intramental) activity underpins cognitive development (Vygotsky, 1962), and we suggest that this relationship is also crucial to the success of creative endeavours.

One effect of the growing influence of socio-cultural theory in developmental psychology and educational research has been to bring closer together some previously separate strands of research, for example that on metacognition and self-regulation (e.g. Whitebread et al., 2007; Dignath et al., 2008) and that on collaborative learning and pedagogy (e.g. Howe, 2010; Mercer & Hodgkinson, 2008). Crucially, the paper will explain how concepts such as 'interthinking', the 'intermental development zone', and 'exploratory talk' (see for example Mercer and Littleton, 2007) can be used to develop sociocultural theory and so help shed light on the nature and significance of collective, creative thinking in real-life settings. In this context consideration will be given as to how space for dialogue can be opened up, extended and deepened – drawing on established ideas such as the importance of establishing and maintaining 'dialogic space' (Wegerif, 2010). Our theoretical discussion will be grounded in empirical examples from various settings including family homes, primary schools, art collectives, musical rehearsals and workplaces. A key focus will be how people use language (and other modes) to achieve creative solutions to problems, generate new ideas and produce new objects together. Thus our exploration will foreground the processes by which people not only appropriate ideas and their cultural heritage but: 'through their contributions to collaboratively undertaken activities, transform in small or large ways, the situations in which they act and the resources that mediate those activities, thereby opening up possibilities for transforming, even if only slightly, the culture as a whole' (Wells and Claxton, 2002 p.8). Our concern is thus with the renewal of culture as well as its reproduction. Furthermore, through our consideration of how people modify, refine and improve culturally valued resources we will explore a tension in socio-cultural theory: between education as enculturation and education for originality, creativity and autonomy. We will thus be discussing how the concept of creative agency can be reconciled with the predominant emphasis on appropriation and enculturation that is a central feature of socio-cultural theory (Wells and Claxton, 2002 p.8), and with recent ideas about the essentially social nature of human intelligence (the 'social brain').

A second focus will be on how an understanding of creativity as social and communicative, as well as cognitive, should influence pedagogy and educational practice more generally. We will explore how teachers can be enabled to foster and encourage the development of learners' ideas and conceptual understanding whilst meeting their responsibilities to ensure that students master the knowledge and skills that are culturally valued. We will also argue for the crucial importance of education developing children's metacognitive awareness of learning and creative endeavour as skilled, collective pursuits. The relevance for this field of study of socio-cultural theory, and methods for analysing talk and interaction derived from that theory, will be critically discussed.

PAPER PRESENTATION

Differently Structured Advance Organizers Lead to Different Learning Outcomes

Johannes Gurlitt, University of Freiburg, Germany; Sebastian Dummel, University of Freiburg, Germany; Sylvia Schuster, University of Freiburg, Germany; Matthias Nuckles, University of Freiburg, Germany

Does the specific structure of initially presented advance organizers make a difference for learning outcomes? Two experiments challenge the view that effects of advance organizers can be explained solely by assimilation theory. The first experiment presents evidence that the construction of proto-schemata through specifically structured advance organizers facilitates learning outcomes, compared to a less structured advance organizer. The second experiment extends this claim and presents evidence that specifically structured and embellished advance organizers do not only facilitate close but also far transfer. These results support the view that well structured and embellished advance organizers can facilitate the construction of proto-schemata and thus can be more than the activation of specific concepts in long-term memory.

What would be a beneficial way of beginning a lesson on different statistical tests? Using specifically structured advance organizers is one possible answer. Advance organizers can be conceptualized as pedagogic tools that bridge the gap between what learners already know and what learners need to know (Ausubel, 1968, 2000). From a theoretical point of view, this study poses the question whether different structures of advance organizers using similar concepts lead to different learning outcomes after a text study phase. This would challenge the view that effects of advance organizers can be explained solely by the activation of concepts. Instead we propose the view that in addition to the activation of available concepts, specific structures of advance organizers facilitate the construction of a preliminary schema (later referred to as a proto-schema) about the topic to be learned.

Overview about the experiments and hypotheses

Varying the structure of the advance organizers, the following competing hypotheses about effects on learning outcomes are proposed: The concept activation hypothesis would predict no differences in learning outcomes assessed after a text study phase, because the advance organizers include similar concepts. The proto-schema facilitation hypothesis is based on the idea that well structured advance organizers should facilitate inductive processes to construct proto-schemata - and thus outperform less structured advance organizers. The related but more detailed focused proto-schema facilitation hypothesis is based on the idea, that even though the paragraphs of the advance organizer are structured in a way to facilitate inductive processes, some learners may not process or see the defining key-features of the respective problem categories. This hypothesis would predict that in addition to the well structured organization of the advance organizer, guidance towards the processing of specific key-concepts may be necessary to enhance learning outcomes compared to a less structured advance organizer.

Method

Forty-eight undergraduate psychology students advance organizer, 2) a well structured and key-concept emphasizing advance organizer and 3) a less structured advance organizer used as a baseline condition. Firstly, learners completed a pretest. One week later, learners studied one of three different advance organizers, completed a sorting task, read an instructional text and finally completed the posttest. Quilici & Mayer (1996, 2002). This paradigm is basically a contrasting cases approach: For the well-structured condition, the same surface story is used for different categories and thus facilitates the differentiation based on deep-level features. In addition, different surface stories are used inside the same category, thus emphasizing the invariant of the specific category despite different surface stories. In the less structured condition, six different cases were used thus making it more difficult to infer similarities within and differences between the respective categories. To emphasize certain key-concepts in the well structured and key-concept emphasizing group, we adapted a paradigm used by McDaniel and Einstein (1989) where letter-completion tasks were used to facilitate the processing of individual idea units to complement relational processing. Following the study of the advance organizers, all three groups completed a sorting task to assess potentially constructed proto-schemata. Then the statistics text was studied, followed by a posttest.

Results and Discussion

As an effect size measure, we used partial η^2 (Cohen, 1988). Based on the hypotheses, a priori contrast weights were assigned to the experimental conditions and a contrast analysis was conducted (Rosenthal, Rosnow, & Rubin, 2000). Following the proto-schema construction hypothesis, an increase in the sorting score as a measure for the degree to which students possess or acquired structure-based schemas for the statistics problems were observed after reading the well structured advance organizers but not or less in the less structured advance organizer condition, $F(1,44) = 5.08$, $p = .03$; $\eta^2 = .10$. The primary interest of this study was whether the well-structured advance

organizers fostered learning outcomes in the posttest compared to the less structured advance organizer. The results of the analysis was in line with the proto-schema construction hypothesis: the planned contrast showed that the well structured advance organizer groups outperformed the less structured advance organizer group in the posttest $F(1,44) = 4.47, p = .09$. Supporting the role of proto-schemata for the final learning outcomes, the correlation between the sorting scores assessed after studying the advance organizer and the final learning outcomes was significant $r(48) = .43, p = .001$. The "pure" well structured advance organizer was not enough to yield a reliable advantage compared to the less structured advance organizer in the posttest $F(1,44) = 2.80, p = .10$. However the well structured and key-concept emphasizing advance organizer showed a reliable advantage compared to the less structured advance organizer in the posttest $F(1,44) = 4.1, p = .09$. In summary, the comparison of well structured and less structured advance organizers indicated that well structured advance organizers facilitated the construction of proto-schemata and learning outcomes. This supports the value of the proto-schema construction view about advance organizers. In addition, the results of this experiment support the hypothesis, that a focused processing of relevant key-concepts was necessary to yield a reliable effect on learning outcomes and thus supports the more detailed focused proto-schema facilitation hypothesis. These results were replicated and extended (e.g. close and far transfer learning outcomes) in a second study that will also be presented. In conclusion, both experiments indicated that prior knowledge activation can be more than the activation of concepts. Different structures of advance organizers using similar concepts lead to substantial differences in learning outcomes. Therefore advance organizers should be differentiated according to the specific structure and task to be completed.

PAPER PRESENTATION

Singing against the tide? Gender beliefs, and expectations of conformity in school activity choice.

Penelope Watson, The University of Auckland, New Zealand; Christine Rubie-Davies, University of Auckland, New Zealand; John Hattie, The University of Auckland, New Zealand

Peer beliefs and expectations about gender identity, gender role and gender-role conformity can limit participation in school activities, mediate stereotype threat, and prompt awareness of it in targets when blatantly expressed. Whereas previous research on stereotype threat has concentrated on helping targets alleviate its effects, this study sheds light on the perpetrators' experience, revealing the need to challenge deep-seated beliefs which lead to stereotyping and prejudice. A new scale comprising both qualitative and quantitative items was employed, to explore how participant groups (out-group peers, teachers, choir director, and choristers), in nine participating school populations varied in terms of sex-typing, beliefs and expectations about gender-role and gender-role conformity, the extent of awareness of prevailing stereotypes, the extent to which those stereotypes were endorsed, and perceptions of the beliefs and expectations of others with regards to gender-role and gender-role conformity. The findings identified how beliefs and expectations about gender identity related to attitudes towards gender-role transgression within different school cultures, and ultimately limited choice of school-based activities for adolescents. This evidence reveals implications for change to practices which may currently augment gender-role conformity in schools and limit pupil outcomes. As well, it adds to research conducted in the field of stereotype threat in a real world setting and importantly, explores the link between stereotypic beliefs and wider held prejudices.

Stereotype threat research (e.g., Schmader, 2010; Steele, 1997; Steele & Aronson, 1995) has focussed almost exclusively on the target's experience. Other research has revealed the effect of beliefs and expectations on student outcomes (Rubie-Davies, Hattie, & Hamilton, 2006), and the importance of peer expectations in adolescence (Wigfield & Wagner, 2005). In two previous studies conducted with boys in choirs, this researcher revealed that beliefs and expectations of adolescent out-group peers had the power to mediate stereotype threat, and when made blatantly salient triggered awareness of it in targets. Moreover, while overt prejudice and stereotyping declines, but subtle stereotypic forces persist (Wolfe & Spencer, 1996), it seems timely to extend the investigation of stereotype threat to the experience of the perpetrators.

This present study aimed to identify beliefs about gender identity and gender role, and expectations of gender-role conformity in terms of school-based activity choice, by addressing three research questions:

1. Do beliefs about gender identity and gender roles, and expectations of activity-based gender-role conformity differ between four participant groups (out-group peers, staff, choral directors and choristers)?
2. To what extent do participant groups endorse stereotypical comments about gender roles?
3. To what extent are participant groups aware of stereotypical gender-roles associated with activities?

Participants (n = 1215) from nine high schools, comprised four groups: teachers (n = 95), choir directors (n = 10), out-group peers from all levels in each school (n = 743), and choristers drawn from eleven male, female and mixed choirs across the nine schools (n = 367). A new four-part scale (The Gender-Role Beliefs and Expectations Questionnaire) was administered yielding both quantitative and qualitative data. All alphas were above .65 providing confidence in using the data in subsequent analyses.

A moderate positive correlation between two factors comprising Part A of the scale (Gender Self-Definition and Gender Self-Acceptance), $r = .60$, n 1215, p Pacific Island males), and weaker for females (but not Pacific Island and Maori females), diminished with age, and was weakest for rural females. Qualitative data triangulated these data confirming that stereotypical ideas of females as objectified and males as agentic prevailed among adolescents.

Cross-tabulations for Part B of the scale revealed the perception that some activities are gendered exclusively male e.g., rugby, and exclusively female e.g., netball (both national games in New Zealand). However, other activities were perceived to be engaged in by both sexes, but felt to be predominantly feminine domains e.g., choir, or predominantly masculine domains e.g., football. Participants perceived that 'others' held a more rigid expectation of gender conformity and would be less likely to desire change than themselves in terms of gender equity in activity choice. Males in single sex male choirs had the most gender-equitable view toward activity choice of all participant groups, females in single sex female choirs were the strongest supporters of gender-role conformity in activity choice, and males in mixed choirs registered the sharpest awareness of the stereotypical views of 'others'.

Ten stereotypical comments comprising Part C of the scale yielded interesting predictive correlations. Where there was a significant endorsement of a comment which supported males' engagement in a feminine domain, this was often associated with indications of support for males' engagement in other feminine domains. Similarly, where a comment reflecting a stereotypical expectation of gender-role conformity was endorsed, this was often associated with endorsement of other such comments. Out-group peers registered the highest mean for endorsing the comment that 'boys in choirs are sissies [weaklings]', and males in single-sex choirs showed the least inclination to endorse comments supporting gender-role conformity.

Cross-tabulations were calculated for the data comprising Part D of the scale: participants reported that a Physical Game scenario was related strongly to boys (71.4%), minimally to girls (4.8%), and moderately to both sexes (23.8%), and that a Vocal Performance scenario was strongly linked to girls (63.7%) minimally to boys (8.3%), and moderately to both sexes (28%). Males (notably Pacific Island and Maori males) strongly confined their scenario choices to gender boundaries, and females much less so. Chi-Square tests for independence indicated significant differences between responses for both scenarios, by gender, ethnicity and age level.

The findings of this study shed light on beliefs and expectations about gender roles which limit choice for young people, the interface between gender stereotyping and adolescent identity formation, and add to stereotype threat research in a real world context, across a range of cultural settings and with a substantial sample. Little research has investigated the connection between stereotypic beliefs and wider prejudicial attitudes (Sherman, Stroessner, Conrey, & Azam, 2005). Thus, it seems fruitful to address not only the lot of the targets, of stereotype threat but also investigate the perpetrators' beliefs and expectations in order to attack both stereotype threat, and the globally-felt limitations of gender prejudice at their roots.

PAPER PRESENTATION

Students Leaving the STEM Pipeline

Hanke Korpershoek, University of Groningen, Netherlands; Hans Kuyper, University of Groningen, Netherlands; Greetje Van der Werf, University of Groningen, Netherlands; Roel Bosker, University of Groningen, Netherlands

The main aim of the present study was to find an answer to the question why some suitably qualified students do not continue their education in science-oriented studies in higher education, despite their previous interest in science-related topics in secondary education. The research was based on the multi-attribute utility theory, using an approach related to the theory of reasoned action (Fishbein & Ajzen, 2010). The study included 477 students who had taken basic or advanced math/science courses in secondary education, but who did not choose a STEM study in higher education (STEM stands for science, technology, engineering, and mathematics). The attitudes of these students towards STEM studies were compared with their attitudes towards their current (non-STEM) study, while also taking the influence of significant others on these students' study choices into account. As expected, most non-STEM students had chosen the best "suitable" option as regards their attitudes. However, one out of ten non-STEM students had a more favourable attitude towards STEM studies than towards their current study. Particularly girls who had taken advanced math/science courses in secondary education belonged to this group. However, the hypothesis that these students had left the STEM pipeline because of the advice of significant others was not confirmed.

Choosing a study in higher education is an important decision in the light of a student's future career. We therefore expected that this choice is a fairly rational one. At some occasions however, people diverge from making rational choices (Kahneman & Tversky, 2000). These are usually situations in which it is impossible to make a full assessment of the situation due to uncertainty about the consequences of certain behaviour. Study choice in higher education is such a situation. Our main interest is why many students who had taken math/science courses in secondary education did not choose a STEM study in higher education (STEM stands for science, technology, engineering, and mathematics).

Aims & theory

We looked into non-STEM students' attitudes towards STEM as compared to their attitudes towards their actually chosen study to find out whether they had opted for the best suitable option as regards their attitudes. The attitude towards math/science has been found to be a significant predictor of students' enrolment in math/science classes and STEM studies (e.g. Second Phase Advisory Point, 2005). Moreover, we searched for the characteristics of students who had chosen a less suitable option as regards their attitudes. In addition, we investigated the influence of significant others (e.g. parents, teachers, and peers) on these students' study choices.

The study was built on the multi-attribute utility theory (MAUT; e.g. Keeney & Raiffa, 1993) on the basis of an approach related to the theory of reasoned action (TRA; Fishbein & Ajzen, 2010). Multi-attribute utility (MAU) models are based on the assumption that the desirability of an alternative depends on how its attributes are evaluated, particularly, the subjectively most important attributes. TRA states that attitudes towards certain behaviour are the result of balancing all advantages and disadvantages associated with this behaviour. It suggests that if people evaluate certain behaviour as positive and want to comply with significant others who want them to exhibit this behaviour, their intention to do so will be stronger than when their attitude is less favourable and/or when they perceive the social influence as weaker.

Method

The data used in the present study were collected as part of a large-scale longitudinal study in the Netherlands, the "Cohort Studies in Secondary Education" (VOCL'99). In this cohort study students are being followed in their educational career from the 7th grade onwards, until they have completed their full-time education. The current study included students that had chosen a non-STEM study in higher education (e.g. medicine, law, economics) and met the criteria for entering a STEM study in higher education (e.g. they had taken their Final School Examinations in advanced mathematics, chemistry, and physics). This procedure resulted in a sample of 477 students of which 340 were girls and 137 boys.

A follow-up questionnaire was used to collect information regarding students' study choices and several attitudinal variables. We used some constructs from TRA to measure the non-STEM students' attitudes towards STEM studies in higher education. We have focussed on students' attitudes towards the study they actually opted for, towards science studies (e.g. mathematics, physics, and chemistry), and towards technical studies (e.g. industrial engineering, architectural engineering, and electrical engineering). We searched for the students' "optimal" choices as regards their attitudes towards the three alternatives. We used several Likert-scale items, measuring students' stereotypes of science-oriented studies (e.g. "I think a technical study is [very easy – very difficult]") and their perceptions of their current (non-STEM) study (e.g. "Do you find your study difficult or easy?"). Moreover, we measured the importance they ascribed to items as regards choosing a study ("I find the difficulty level of a study [not at all important – very important], their motivation to comply with advice from significant others, and their normative beliefs (i.e. their perception of other people's recommendations).

Results

As expected, most non-STEM students had chosen the best "fitting" option as regards their attitudes. For most students, a STEM study was not an attractive alternative as compared to the study they had actually chosen. However, one out of ten non-STEM students, particularly girls who took the more advanced math/science courses in secondary education, had a more favourable attitude towards STEM studies than toward their current study (mainly with regard to choice-options, content, and expected achievement). In addition, we found that non-STEM students' attitude towards technical studies was more favourable than their attitude towards science studies.

Furthermore, we investigated whether the non-STEM students who would fit STEM studies were more strongly influenced by significant others to choose a non-STEM study than the other non-STEM students. Our hypothesis that significant others had advised these students to leave the STEM pipeline was, however, not supported by our data. Although we expected a stronger influence with respect to the current non-STEM study among the STEM candidates, we found that they were more strongly influenced than other non-STEM students to choose science or technical studies. However, they had nevertheless chosen a non-STEM study despite the advice of significant others.

In conclusion, the procedure of combining MAUT and TRA is new in the research field. It has proven to be a valuable and useful approach to enhancing our general understanding of why some suitably qualified students do not continue their educational career by choosing a STEM study. The results of our analyses indicate that there are specific student groups, such as girls who took advanced math/science courses in secondary education, which would fit STEM studies in terms of their attitudes and abilities. This information could be used in offering these STEM candidates adequate counselling in the future.

PAPER PRESENTATION

Validation of a German version of the Epistemological Beliefs Inventory (EBI)

Bjoern Mokwinski, School of Computing Science, Business Administration, Economics, and Law, Germany; Karin Rebmann, Business Administration, Economics and Law, Germany; Manuela Paechter, Karl-Franzens-University Graz, Austria; Yvonne Hanekamp, Carl von Ossietzky University Oldenburg, Germany; Daniel Macher, Karl-Franzen-Universität Grz, Austria

Up to now, German researchers experience the investigation of domain-independent epistemological beliefs as an unsolved problem, since there is a lack of reliable and valid questionnaire. Therefore, the Epistemic Beliefs Inventory (EBI) - an Anglophone questionnaire developed by Schraw, Bendixen, and Dunkle (2002), which showed an invariable factorial structure in several samples and had satisfactory retest reliability – was translated into the German language. Afterwards, its psychometric properties were investigated in a series of pilot studies. Since this translated version showed unsatisfactory psychometric properties, new items were developed for a revised questionnaire version. The

development of these items was based on content analyses of 90 qualitative interviews with students. The psychometric properties as well as the factorial structure of the newly derived questionnaire were investigated in a sample of 471 students in Germany. Exploratory factor analyses showed a structure with four factors. This structure could be confirmed by means of confirmatory factor analysis in a sample of 364 students in Austria. Also, the questionnaire showed satisfactory retest-reliability (measured in a subsample of 222 students one month after initial testing). Another aim of the survey was to analyze criterion-related validity. Besides the revised EBI, the German students filled in a questionnaire on cognitive learning strategies. As expected, students with more sophisticated beliefs tend to use higher order cognitive learning strategies, while students with less sophisticated beliefs prefer the use of less complex strategies. Taken together, the empirical results argue in favor of the new instrument with regard to its reliability and validity.

Overview and aims of the research

Epistemological beliefs are personal beliefs about knowledge and the acquisition of knowledge. As subjective theories of an individual, they have the function of directing and controlling actions. Therefore, they are linked to numerous aspects of academic learning, e.g., to how students approach learning processes or how they view their role as learners. Researchers investigating epistemological beliefs have encountered the problem of developing a reliable and valid measure of these beliefs. Schraw, Bendixen, and Dunkle (2002) developed a questionnaire EBI (Epistemic Beliefs Inventory) that assumes that epistemological beliefs can be described by five dimensions: omniscient authority, certain knowledge, quick learning, simple knowledge, and innate ability. In a validation study, Schraw, Bendixen, and Dunkle (2002) could confirm these five dimensions by means of explorative factor analysis. In comparison to other epistemological beliefs instruments, the EBI was one of the few instruments which showed an invariable factorial structure in several samples and which had satisfactory retest reliability. When transferring questionnaires into a different language and cultural context it is necessary to investigate their psychometric quality. For a study in German-speaking countries the EBI was translated and its psychometric properties were investigated in a first series of pilot studies. In these studies, the translated version showed partly unsatisfactory psychometric properties (e.g., item difficulties or varying factorial structures). One factor assumed by Schraw, Bendixen, and Dunkle (2002) consistently did not show in the factor analyses, namely certain knowledge. Due to these difficulties, new items were developed for a revised version of the EBI. First, a pilot study was conducted in which qualitative interviews with 90 students were carried out. Based on the results of content analyses of the interviews, new items and a revised German version of the EBI were developed. It consisted of 14 items of the original questionnaire and 17 new items (altogether 31 items). The aim of the present research is to analyze the psychometric properties of this revised EBI version by four steps: Investigation of (1) item properties and factorial structure, (2) retest reliability, (3) the invariability of the factorial structure in another sample, and (4) criterion-related validity. For step 4, it was investigated to what extent epistemological beliefs correlate with the use of cognitive learning strategies. As a result of the present research, a German questionnaire for measuring epistemological beliefs in student population was to be developed.

Methodology

Item properties and factorial structure: Psychometric properties and the factorial structure of the revised EBI were investigated in a sample of 471 university students in Germany from social sciences and economics. All items showed satisfactory item difficulties between 0.20 and 0.80. Orthogonal exploratory factor analysis with Varimax rotation was carried out to uncover the underlying structure of the variables. As a criterion factor loadings of ≥ 0.30 were defined as significant. Factor analysis showed a solution with 15 items and four factors: Quick learning (five items), omniscient authority (three items), simple knowledge (four items), and innate ability (three items). These factors explained 41,59 % of the variance.

2) Retest reliability: For the analysis of the retest-reliability, 222 students of the former investigation filled in the revised EBI version (one month after the first testing). The four factors showed satisfactory retest reliability coefficients which resembled those of the original EBI questionnaire.

3) Invariability of the factorial structure: The stability of the revised EBI version was investigated in a German-speaking sample of 364 university students in Austria from different majors from social sciences and economics. Confirmatory factor analysis was used to test the model fit of the factorial structure found in the German sample. The factor analysis showed satisfactory model fits when one variable of the factor "structure" was removed (RMSEA=.046, CFI=.974, SRMR=0.047). These results recommend measuring the factor structure by three items (instead of four as recommended by the factorial structure of step 1).

4) Criterion-related validity: It was investigated how the four factors of the revised EBI version correlate with the application of cognitive learning strategies. In order to investigate the application of cognitive learning strategies a German inventory (LIST) was used. To analyze this relationship a canonical correlation was performed between the

epistemological beliefs scales and identified cognitive learning strategy scales. The results show that the scales are related to each other. Altogether, the results indicate that students with more sophisticated beliefs tend to use higher order cognitive learning strategies, while students with less sophisticated beliefs prefer the use of less complex strategies.

Theoretical and educational significance

The questionnaire measures four dimensions of epistemological beliefs presented in this research, quick learning, omniscient authority, simple knowledge, and omniscient authority. The factor "certain knowledge" could not be found in the analyses. The items of this dimension describe whether knowledge is stable over time. Probably, these items did not reflect the learning experiences of students who are confronted with changing knowledge in their fields of study and who might be faced with the task to permanently acquire new knowledge. The four factorial structure of the revised EBI version could be confirmed in another German speaking sample. Retest reliability of the factors were satisfactory and it could be shown that the factors correlate with different types of learning strategies. Altogether, one may conclude that a questionnaire has been developed which enables the assessment of epistemological beliefs in German speaking samples. The newly derived questionnaire can be used by researchers to measure general, domain-independent beliefs about knowledge and the acquisition of knowledge. The questionnaire may also be useful for practitioners in the field of education. Knowledge about epistemological beliefs gives teachers a chance to gain an insight into their students' learning processes and motivation. Consequently, students' epistemological beliefs give teachers an important starting point to encourage their students to learn – both at school and in higher education.

PAPER PRESENTATION

Investigating text features of online information affecting laypeople's perception of scientificness

Eva Thomm, University of Muenster, Germany; Rainer Bromme, Universitat Muenster, Germany

If laypersons search the Internet in order to make a knowledge-based decision on issues of daily life (healthcare, environment protection), they often come across a vast amount of information which contain scientific concepts and thus are frequently beyond their own everyday knowledge. Therefore, laypeople rely on the knowledge of experts. Identifying and accurately evaluating online information of experts demands for an understanding of the narrative conventions of scientific discourse. Studies examining individuals' judgments about the veracity and credibility of online information demonstrate that users particularly attend to superficial features. Since text features may work as cues for 'scientificness', it is crucial to analyze individuals' grasp of narrative norms of scientific discourse and its influence on the evaluation of online information. The present study investigates laypeople's understanding of characteristics of scientific discourse examining whether features typical for scientific discourse affect laypersons' perceived 'scientificness' of online information and whether they recognize these attributes as indicators of adequate discourse. Undergraduates read scientific and factual presentations of texts about phenomena of either global warming or medicine, each embedded within a scenario which required participants to judge the perceived scientificness of the online text. The results are analyzed regarding differences in perceived scientificness depending on the presentation. Its relationship to text credibility, acceptance of text contents and behavior dealing with online information is assessed. Educational implications for fostering laypeople's understanding of conventions of scientific discourse as part of science are deduced and discussed with regard to its meaning for the evaluation of online information.

Within modern societies, the rapid growth of available knowledge comes along with the increasing differentiation of scientific knowledge. To make knowledge-based decisions about issues of private and public life (i. e. health care or forming an opinion about environment protection), individuals have to handle scientific concepts which are far too complex to be deeply understood by a layperson (Kienhues, 2010). Therefore laypersons must rely on experts based on their own fragmentary understanding of such issues (Keil et al., 2008). The Internet simplifies the accessibility and availability of expert information about any science-based topic. It offers many useful documents, but it also provides documents of questionable quality and doubtful authorship. Thus, its use reinforces the necessity to evaluate the veracity of the retrieved information as well as the pertinence and credibility of the author (Bromme et al., 2010). The evaluation of science-based information may demand for a –at least coarse- understanding of the norms of scientific discourse which are shared and expected within the expert community. However, most studies which examined individuals' judgement of online information focussed on the question whether individuals check the author of online texts (sourcing) or attend to the surface features as for example website design and scientific language of text

(Eysenbach & K hler, 2002; Eysenbach, 2008; Flanagin & Metzger, 2007; Fogg et al., 2002). It has been less often analyzed whether laypersons have a coarse understanding of what makes a text a scientific one and if such features contribute to veracity judgements (but see Ackermann & Leiser, 2010; Weisberg et al., 2008). We are especially interested in those features of scientific texts which reflect the discursive and social nature of scientific knowledge production (Goldman, 2003; Longino, 2002). Examples are: Citations (Harr  , 1990), combining knowledge claims with references to the methods used, and a wording which emphasizes the establishment of facts by the researcher ("it has been observed that there is a relationship between amount of traffic and CO 2"), instead of a pure factual statement ("there is a relationship between....").

The present study focuses on laypeople's notions about characteristics of scientific discourse and addresses two goals: Firstly, the study aims to analyze whether features typical for scientific discourse affect laypersons' perception of the 'scientificness' of online information concerning science-based topics.

Secondly, it investigates whether laypeople recognize and identify these text features as being indicators of true scientific discourse, showing a coarse understanding of the narrative norms.

Furthermore the relationship between perceived scientificness, text credibility and acceptance of text contents is examined.

Undergraduates studying different subjects participated in the study. They were equally assigned to four experimental conditions in a 2x2-repeated measurement design with the between-subject factor scientific domain (medicine vs. global warming) and the within-subject factor text type (factual presentation vs. scientific presentation). Expository texts about two phenomena of global warming and of medicine were created. For each text, two versions were generated depicting a factual or a scientific presentation of the phenomena: The scientific presentation was enriched with citations and mentioned applied scientific methods depicting scientific accomplishment as a result of discourse, in contrast, the factual presentation contained neither citations nor methods describing research results as given facts. While text type varied, content information remained the same. Participants read one version of both text types of either phenomena of global warming or medicine, each embedded within a scenario which required participants to judge the perceived scientificness of the online text. Furthermore, they were instructed to mark text passages which indicated the scientificness of the text from their point of view. Text credibility and acceptance of text contents were measured. Participants additionally answered items asking for their behavior dealing with scientific online information.

The results are analyzed regarding differences in perceived scientificness depending on text type. Its relationship to text credibility, acceptance of text contents and behavior dealing with online information is assessed. The data are compared across scientific domains and text types.

Educational implications for fostering laypeople's understanding of conventions of scientific discourse as part of science and of scientific culture are deduced and discussed with regard to its meaning for evaluating online information.

PAPER PRESENTATION

Development of an instrument measuring interpersonal trust in Dutch schools

Maren Thomsen, University of Amsterdam, Netherlands

The aim of the present study was to develop an instrument to measure trust between teachers and between teachers and supervisors in SSVE schools in the Netherlands. Most measurements predominantly measure the belief of the trustor about the trustworthiness of the trustee, asking about characteristics of the trustee, this indicates a problematic mixture of antecedents of trust and the concept itself in the operationalization. Two scales to measure interpersonal trust in SSVE schools between teachers (Trust-T) respectively teachers and supervisors (Trust-S) were developed, based on earlier work of Gillespie (2003). The scales contained questions about teachers' willingness to take a risk in situations that are important to them and in which they are vulnerable and dependent on the other party. 113 SSVE school teachers filled in a questionnaire which included the two trust scales. The average age of the respondents was 50 years (SD=9.5) and 46% was female. A confirmatory factor analysis, using structural equation modeling, was conducted. After model modifications a satisfactory model fit was reached. The model indicates a good construct validity of the used measure of trust.

Aims

This study is part of a larger study about the impact of trust in schools for senior secondary vocational education (SSVE) in the Netherlands on the relationship between organizational characteristics and teacher's work-related behaviors. The present study aims to develop an instrument to measure trust between teachers and between teachers and supervisors in SSVE schools in the Netherlands. Trust is a construct that has been studied for a long time and in different disciplines (Dietz & Den Hartog, 2006). It is a very complex concept and up to date there is no consensus about the definition of trust. However, most definitions include the willingness to be vulnerable of the trustor in the relationship with another party (e.g. Tschannen-Moran & Hoy, 1998). Trust between people is usually referred to as interpersonal trust and trust in an institution as system trust (Luhmann, 1979). This study focuses on interpersonal trust. There is a great variety of different operationalizations of interpersonal trust. On the one hand this may reflect the large multidisciplinary interest in the concept; however, on the other hand, it may reflect dissatisfaction with the existing measurements (Dietz & Den Hartog, 2006). Most measurements predominantly measure the belief of the trustor about the trustworthiness of the trustee, asking about characteristics of the trustee (e.g. Nyhan & Marlowe, 1997; Robinson, 1996; Hoy & Tschannen-Moran, 2003). Depending on the definition of trust, this indicates a mixture of antecedents of trust and the concept itself in the operationalization. These measures usually have good internal reliability but they actually do not capture the willingness of the trustor to be vulnerable to the trustee, a core element of most definitions of trust. One of the exceptions is the instrument developed by Gillespie (2003). In her work trust is designed specifically to assess the decision to trust. The items are worded as behavioral intentions (Dietz & Den Hartog, 2006). Dietz and Den Hartog (2006) recommend to include measures of the decision to trust in trust measurements. Hence, to measure the intention to act based on trust, which should be a consequence of the belief that the trustee is trustworthy.

Taking these considerations into account, the aim of this study is to further develop and verify Gillespie's trust measurement to measure interpersonal trust in an educational context.

Methodology

Two 10-item scales to measure interpersonal trust in SSVE schools between teachers (Trust-T) respectively teachers and supervisors (Trust-S) were formulated, based on earlier work of Gillespie (2003). The items were formulated in Dutch. The scales contained questions about teachers' willingness to take a risk in situations that are important to the teacher and in which they are vulnerable and dependent on the other party. The trust scales were rated on a 5-point Likert-type scale, ranging from 1 (completely disagree) to 5 (completely agree). For item inclusion in the final scale the

items were first critically examined by three expert professionals. On the basis of their comments, three items were eliminated, and four questions were reworded. The final Trust-T scale consists of 9 items and the final Trust-S scale of 8 items. A complete list of items can be found in table 2. A questionnaire was distributed to 430 teachers of seven SSVE schools. 26% of the teachers returned the questionnaire (N=113). The average age of the respondents was 50 years (SD=9.5) and 46% was female. The questionnaire included, next to other items, the Trust-T scale and the Trust-M scale. A confirmatory factor analysis, using structural equation modeling with Mx (MxGui Version 1.7.03), was conducted to further evaluate the suitability of the items, and whether the proposed dimensions had some attributes that could provide a coherent interpretation of the construct. A two-factor model was fitted to the covariance matrix. To guide model modifications when the fit of the factor model was poor, next to the standardized factor loadings, the difference between the observed and the estimated correlations (correlation residuals) were used as well as theoretical considerations.

Results

The data fitted the simple two-factor model poorly: $\chi^2_{(118)} = 270.71$, $p = 0.000$ and RMSEA=0.116 (90% CI [0.0979, 0.1343]). After adjusting the model step by step using correlation residuals as indicator for poor representation of the data and considering possible theoretical explanations and validations for the changes the model showed a satisfactory fit: $\chi^2_{(110)} = 161.138$, $p = 0.001$ and RMSEA=0.070 (90% CI [0.0448, 0.0918]). The model indicates a good construct validity of the used measure of trust. All standardized factor loadings are significant and most of them are around 0.7, indicating high indicator (item)- factor correlations. The parameter estimates are presented in table 2. The relatively high standardized factor loadings suggest convergent validity and the relatively low factor correlation (0.3429) indicates discriminant validity (Kline, 2005). The internal validity of the measure in the current sample, expressed in Cronbach's alpha is very good (Trust-S scale: 0.91 and Trust-T scale: 0.89). Further, the model supports the assumption, that trust has two sources, the characteristics of the trustee and a general willingness of the trustor to trust others. The former can be found in the clear distinction between the two factors, trust in the supervisor and trust in colleagues. Support for the second assumption is reflected in the significant correlation between the two factors. This correlation indicates that both factors measure a dimension of trust that is independent of the trustee. It is possible that the sample size influenced the results: An upcoming second measure by a larger sample will clarify that.

Relevance

Within this study a measure of trust has been further developed and verified for the educational context. In contrast to commonly used instruments, this measure takes the core element of trust, the willingness to be vulnerable to another party, into account. Using structural equation modeling it has been shown that the instrument is a robust tool to measure interpersonal trust with high convergent and discriminant validity.

PAPER PRESENTATION

Promoting moral development: comparison of two teaching methods

Ulrike-Marie Krause, Saarland University, Germany; Robin Stark, Dept of Education, University of the Saarland, Germany

In this research project, we intended to promote moral development of high school students. One of the most influential approaches of moral education is Lawrence Kohlberg's dilemma discussion which encourages students to systematically reflect on moral conflicts and decisions. This method is based on Kohlberg's cognitive-developmental model of moral stages. New works in the field of moral development and moral education highlight the relevance of emotions for moral judgment and moral action. In the present study, we implemented modified versions of the dilemma method. In a quasi-experimental field study, we compared two teaching methods: One was more cognitively oriented (with a focus on moral argumentation; e.g. discussion of moral decisions), and the other one was more affectively oriented (with a focus on empathy, e.g. in role plays). The study was conducted in two high school classes (9th grade; students were around 15 years of age). In one of the classes ($n = 28$), the cognitive approach was implemented, in the other class ($n = 27$), the affective method was used. The two classes did not differ concerning relevant student characteristics (age, gender ratio, moral stage according to Kohlberg etc.). Results indicated that the affective approach was superior: Students' moral argumentation and perceived performance were better in this group. This study can stimulate further research on affective activation and support (as a supplement to cognitive activation and support) in moral education.

Aims

In this research project, we intended to promote moral development of high school students. One of the most influential approaches of moral education is Lawrence Kohlberg's dilemma discussion which encourages students to

systematically reflect on moral conflicts and decisions (Blatt & Kohlberg, 1975). This method is based on Kohlberg's (e.g. 1984) cognitive-developmental model of moral stages. New works in this field highlight the relevance of emotions (especially of empathy) for moral judgment and moral action (e.g. Haidt, 2001; Hoffman, 2000; Keller, Brandt & Sigurdadottir, 2010). Against this background, we developed two modified versions of the dilemma method: One had a cognitive focus, whereas the other one was more affectively oriented (see below). These two approaches were examined in an intervention study. The following research questions were addressed:

- (1) To what extent do the teaching methods promote moral judgment?
- (2) To what extent do the teaching methods influence motivational aspects?

Methodology

We conducted a quasi-experimental field study in two high school classes (9th grade; mean age: 14.62 years, SD = .62). In one of the classes (n = 28), the cognitive approach was implemented, in the other class (n = 27), the affective method was used. The teaching unit was conducted by social studies teachers, based on a written guide; besides, research assistants were present in the classrooms during the entire intervention. The study was conducted within a time frame of three weeks (six times 45 min, i.e. two 45 min sessions per week).

In the first session, a pretest and a questionnaire were administered. In the pretest, students had to analyse a moral dilemma; based on students' analyses, moral stages according to Kohlberg were determined. The questionnaire was used to measure motivational aspects. Topic interest was recorded by a 4-item scale (e.g. "I am interested in moral issues"; Cronbach's alpha = .69), the students' self-concept concerning moral issues was gathered by a 3-item scale (e.g. "I have an idea of what is relevant for moral decisions"; Cronbach's alpha = .82).

In the second to fifth session, the two dilemma-based teaching methods were implemented. The cognitive approach mainly consisted of moral argumentation, reflection and discussion, whereas the affective approach embraced role plays and other creative tasks that required empathic activity.

In the last session, a posttest was administered. As in the pretest, students had to analyse a moral dilemma, and moral stages were determined. Each statement of the students' analyses was coded; then the highest acquired stage and the most frequent stage were identified. Besides, the moral maturity score (Blatt & Kohlberg, 1975) was calculated, which is the sum of the products "percentage x number of the stage"; for example if 50 % of a student's statements can be allocated to stage 1 and 50 % to stage 2, the student gets a moral maturity score of $50 \times 1 + 50 \times 2 = 150$. Moreover, students were asked to evaluate the teaching unit (3 items, e.g. "I liked the lessons on moral decisions"; Cronbach's alpha = .76) and to assess their own performance during the teaching unit on a 15-point scale ranging from "very bad" to "very good".

Findings

The two high school classes did not differ concerning relevant student characteristics, such as age, gender ratio, moral stage t1, topic interest and self-concept (all $p > .20$).

Posttest results revealed a superiority of the affective approach concerning moral stages (see table 1).

A MANOVA with the dependent variables "highest stage", "most frequent stage" and "moral maturity score" indicated a significant effect of the factor "teaching method" ($F(3, 51) = 3.49$, $p = .02$, $\eta^2 = .17$). For each dependent variable, t-tests were calculated which confirmed the significant superiority of the affective approach (highest stage: $t(53) = 2.80$, $p = .01$, $d = .75$; most frequent stage: $t(53) = 2.50$, $p = .02$, $d = .67$; moral maturity score: $t(53) = 2.57$, $p = .01$, $d = .69$).

Tables 2 displays the results on acceptance of the teaching unit and perceived performance.

T-tests showed that there was no significant group difference in acceptance ($t(51) = -.89$, $p = .38$), whereas the difference in perceived performance was significant ($t(38.33) = 2.07$, $p = .04$, $d = .58$).

Theoretical and educational significance

Our findings indicate that dilemma-based moral education can be enhanced by affective methodical elements that are geared towards empathic activity, such as role play or comparable creative tasks (e.g. writing a letter or an e-mail from the perspective of another person). This study can stimulate additional research on affective activation and support (as a supplement to cognitive activation and support) in moral education. In further studies, we will try to replicate our findings and to gain deeper insight into relevant cognitive, affective and social processes.

PAPER PRESENTATION

Teaching practices, self-efficacy, value, peer acceptance, and engagement: A multilevel analysis

Virginie Hospel, Université catholique de Louvain (UCL), Belgium ; Benoit Galand, Université catholique de Louvain, Belgium

This study uses a multilevel framework to investigate the effects of teaching practices (classroom level) on facilitators and indicators of engagement (student level), controlling for classroom composition and individual characteristics, and to test if the effects of teaching practices on indicators of engagement are mediated by facilitators (Skinner, Furrer, Marchand & Kinderman, 2008). Seven hundred and forty-one French-speaking 9th graders from 51 classrooms completed a questionnaire about facilitators of engagement (self-efficacy, task value, peer acceptance), indicators of engagement (emotional, cognitive, behavioural) and dimensions of teaching practices (provision of choice, invitation of student expression and participation, clarity and structure, formative feedback, supportive teacher-student relationships, equality of treatment). Results show that student self-efficacy is higher in classrooms with more provision of choice, perceived task value is higher in classrooms with more formative feedbacks, and peer acceptance is higher in classrooms with more equality of treatment. Moreover, they indicate that equality of treatment has an effect on emotional, cognitive and behavioral engagement above the effects of self-efficacy, task value and peer acceptance. These results are quite consistent with research pointing to the detrimental effects of performance goal structure on student motivation. They also underscore the relevance of separating facilitators and indicators of engagement to better understand the motivational dynamic of the students.

Background and aims

A growing number of studies pointed to the importance of student engagement for achievement and persistence in educational settings (Appleton, Christenson & Furlong, 2008; Janosz, Archambault, Pagani & Morizot, 2008). Engagement is a multidimensional construct including emotional, cognitive, and behavioral components (Fredricks, Blumefeld & Paris, 2004). Recently, Skinner, Furrer, Marchand and Kinderman (2008) introduced a distinction between facilitators (self-related perceptions regarding an activity) and indicators (emotional, cognitive and behavioral reactions during an activity) of engagement. They hypothesised that the effects of contextual factors on indicators of engagement are mediated by facilitators of engagement.

Among potential facilitators, a large number of studies have documented the positive effect of self-efficacy (Bandura, 1997; Linnebrink & Pintrich, 2003), task value (Simpkins, Davis-Kean & Eccles, 2006; Wigfield, Tonks & Klauda, 2009) and peer acceptance (Ladd, Herald-Brown & Kochel, 2009; Juvonen, 2007) on engagement. Among potential contextual factors, several studies have investigated the role of teaching practices. Their results pointed to the positive effect for student engagement of (a) supportive teacher-student relationships and equality of treatment (Roeser, Urdan & Stephens, 2009; Wentzel, 2009), (b) clarity, structure and formative feedback (Guthrie, Wigfield & Perencevich, 2004; Skinner & Belmont, 1993), (c) provision of choices and invitation of student expression and participation (Deci & Ryan, 2000; Reeves & Jang, 2006). However, most available studies related individual perceptions of teaching practices with engagement rather than using a multilevel framework. Doing so, they did not take into account the nested structure of the data (students nested in classrooms and/or schools) and did not allow assessing the contextual or idiosyncratic nature of these links (Marks, 2000).

In the present study, we wanted to use a multilevel analytical framework (a) to assess the magnitude of classroom effect on facilitators and indicators of engagement toward a specific course, (b) to examine the effects of teaching practices in this course (classroom level) on facilitators and indicators of engagement (student level), controlling for classroom composition and individual characteristics, and (c) to test the mediation of engagement facilitators between teaching practices and engagement indicators.

Method

Sample and procedure

Seven hundred and forty-one French-speaking 9th graders from 51 classrooms completed an anonymous questionnaire about their language course.

Measures

Individual socio-demographic characteristics: Gender, age, grade retention, socio-economic status (SES), ethnicity.

Indicators of engagement: Emotional, cognitive and behavioral engagement during language lessons.

Facilitators of engagement: Self-efficacy, perceived task value, and peer acceptance in language course.

Teaching practices: Student perceptions of provision of choice, invitation of student expression and participation, clarity and structure, formative feedback, supportive teacher-student relationships, and equality of treatment between high and low achievers, from their language teacher.

Classroom composition: number of students, school track, gender ratio, ratio of retained students, mean SES.

Results

Multilevel analyses were performed with the HLM6 software, using a stepwise procedure. First, models without predictors were run to estimate the partition of variance between and within classrooms. These analyses indicated significant between-classroom variance for facilitators (from 4 to 16 % of total variance) and indicators (from 12 to 17 % of total variance) of engagement.

Second, models including individual socio-demographic characteristics and classroom composition were run. Girls and students from higher socio-cultural background reported higher self-efficacy, higher task value, and higher emotional, cognitive and behavioral engagement. Moreover, self-efficacy was lower in classrooms with higher mean SES, peer acceptance was lower in classrooms with a larger proportion of retained students, and behavioral engagement was higher in classrooms with a larger proportion of girls. Taken together, these variables generally had only a small effect on between-classroom variance.

Third, perceptions of teaching practices aggregated at the classroom level were added in the models, controlling for the variables introduced at step two. Results showed that student self-efficacy was higher in classrooms with more provision of choice, perceived task value was higher in classrooms with more formative feedbacks, and peer acceptance was higher in classrooms with more equality of treatment. Emotional, cognitive and behavioral engagement were also higher in classrooms with more equality of treatment. At this step, between-classroom variances were largely reduced, but remained significant for self-efficacy, peer acceptance, and cognitive engagement. Fourth, facilitators of engagement were introduced as mediators between teaching practices and indicators of engagement. The effects of equality of treatment on the three indicators of engagement were reduced when controlling for self-efficacy, task value, and peer acceptance, but remained significant for emotional and behavioral engagement. Self-efficacy and task value were significantly associated with the three forms of engagement, but peer acceptance was associated only with emotional engagement. Among all predictors, task value displayed strongest relationship with each component of engagement.

Discussion

The results of the present study support the idea that between-classroom variations in student engagement could be related to variations in teaching practices. Concerning the effect of provision of choice on self-efficacy, results suggest that students interpret choices as a sign of teacher confidence in their capacities and teacher high expectations regarding their progress (Schunk & Pajares, 2009). Concerning the effect of formative feedbacks on perceived task value, results suggest that forms of assessments communicating that making errors is part of the learning process and providing cognitive guidance to master the material help students to value this material (Wigfield et al., 2009). Concerning the effect of equality of treatment on peer acceptance, results suggest that stressing social comparison and fostering competition between students reduce social support among peers (Midgley, 2002). In our sample, equality of treatment seems to be especially important for the three indicators of engagement investigated. This kind of teaching practices has a direct effect on engagement above the effects of self-efficacy, task value and peer acceptance. These results are quite consistent with research pointing to the detrimental effects of performance goal structure on student motivation (Roeser, Eccles & Sameroff, 1998). They also underscore the relevance of separating facilitators and indicators of engagement to better understand the motivational dynamic of the students (Skinner et al., 2008).

PAPER PRESENTATION

Maria Weurlander, Karolinska Institutet, Sweden; Max Scheja, Stockholm University, Sweden; Hakan Hult, Karolinska Institutet, Sweden; Annika Wernerson, Karolinska Institutet, Sweden

Students in medical education have to face suffering and death during their studies. The aim of this study was to explore medical students' experiences of an emotionally strong learning situation: the autopsy. Written accounts from 17 medical students were collected after their first and their third or fourth autopsy. Using a qualitative content analysis, data was coded and grouped into themes. The experience of the first autopsy can be described in terms of 'closeness' and 'distance'. For many students, the human body came very close, either their own physical reactions or reactions to the exposed corpse. For others, who could distance themselves, the autopsy allowed in depth studies of anatomy or pathology. The context was important and the teacher's guidance through the procedure helped generate a positive experience.

Introduction

Research on student learning in higher education have a strong focus on cognitive aspects of learning researching for instance approaches to learning (Marton et al 1985) or experiences of understanding (Entwistle 2009). However, students in medical and health care education meet patients with severe diseases, and have to face suffering and death during their undergraduate education, factors that may influence the learning process compared to a normal "class-room" context. Such situations make a strong impression and can be a very unpleasant experience that students need to process in order to learn what is intended in these situations (Smith & Kleinman 1989, Loftus 1998, Kelly & Nisker 2010). Moreover, the students often have to deal with the unpleasant emotions alone without the support from teachers (Smith & Kleinman 1989, Kelly & Nisker 2010). On the other hand, if these situations are handled well by the teacher, they could be a very good learning experience important in their future profession. A learning situation that is known to have a strong emotional impact on students is the autopsy. However, studies investigating students' experiences of autopsies are rare. Traditionally, autopsies have been a common learning activity in medical education but during the last decades the autopsy rates have been decreasing, resulting in fewer opportunities for students to participate (Hill & Anderson 1991). Clinical teachers and pathologists consider autopsies important for several reasons; to help students consolidate knowledge in anatomy and to understand mechanisms of diseases in different organs, but also to learn how a dead body is taken care of, to get an insight into how an autopsy is conducted and why autopsies are important to learn about disease and treatments (Hill & Anderson 1991, Burton 2003).

The aim of this study was to explore medical students' experiences of an emotionally strong learning situation: the autopsy. During a course in pathology in the second year of undergraduate medical studies, students have the opportunity to attend up to four autopsies.

The research questions were:

How do student experience autopsies?

In what ways are autopsies important learning opportunities?

The research was conducted within an interpretive research tradition and an explorative research design was used to capture students' experiences (Denzin & Lincoln 2003). Qualitative data was collected by means of written accounts from 17 students after attending their first and their third or fourth autopsy (34 accounts in total). The students were asked to describe their experiences of the autopsy and explain if and if so, in what way they were a learning experience. Using a qualitative thematic content analysis, data was coded and grouped into themes (Graneheim & Lundman 2004)

.Preliminary findings

The experience of the first autopsy can be described in terms of 'closeness' and 'distance'. For many students, the first autopsy was an emotionally strong experience where the human body evoked strong feelings. Students felt their own body react to the situation by for example nausea, or described that the dissected corpse with blood and the smell became very close and "real". Other students described it as a surreal experience or that they distanced themselves and tried not to involve their own emotions. For students, who managed to distance themselves from the unpleasantness of the situation, it was an opportunity engage in depth in the study of anatomy or to learn pathology and develop understanding of how diseases manifest themselves in the human body and how a decreased function in one organ affects other parts of the body. Furthermore, the context was important for students' experiences and the teacher had a central role in guiding the students through the procedure, which helped to generate positive learning experiences. Attending the first autopsy seemed to have a strong emotional impact on many students and they needed to process their experiences in order to cope with the situation and learn what was intended by the teachers. Some students coped by focusing on their own emotions and reactions while others tried to adapt to the situation and related to the purpose of the autopsy. The first autopsy seemed mainly to help students to understand the autopsy procedure, and it was during the following autopsies that many students learned to focus on anatomy and pathological changes in the organs. Students got used to the situation and became more and more interested in the

pathologists' search for the cause of death. These findings confirm that the autopsy is an important learning opportunity for students, if they are guided through the procedure and have time to get used to the situation.

Educational significance

The findings of this study suggest that students react differently to autopsies, but find them important. Teachers have a central role in guiding students through the procedures and clarifying the purpose of autopsies to students. This could help students cope successfully with the situation and create better opportunities for learning.

PAPER PRESENTATION

Student-teacher relationships, motivation, and transition into secondary school

Roch Chouinard, University of Montreal, Canada; Normand Roy, University of Montreal, Canada; Francois Bowen, University of Montreal, Canada

The purpose of this study was to document the impact of student-teacher relationships on achievement motivation in the context of the transition into secondary school. A questionnaire was administered three times to 1158 students: At the end of 6th grade (elementary school), at the beginning and the end of 7th grade (secondary school). Latent growth models estimated trajectories for competence beliefs, performance anxiety, utility-value, interest, and mastery goals considering the evolution of student-teacher relationships (increasing or decreasing). Analyses showed that students' achievement motivation in the transition into secondary school largely covariates with student-teacher relationships. Results also support stage-environment fit theory and highlight the link between attachment, connectedness, and achievement motivation.

Previous researches have shown that students' achievement motivation significantly declines during the transition into secondary school. Researchers have documented a general drop of interest for school (Harter, 1996; Simmons & Blyth, 1987) and a rise of performance anxiety in this period (Hirsch & Rapkin, 1987). Domain specific motivation also declines: drop of interest and mastery goals (Eccles, 2007), and of competence beliefs and utility-value of mathematics, language arts and sciences were reported (Harter, Whitesell, & Kowalski, 1992). Some authors have emphasized that the lesser quality of student-teacher relationships in secondary school compared to elementary school partially explains this phenomenon (Eccles et al., 1991; Lynch & Cicchetti, 1997). However, students are affected differently by the transition into secondary school. Some show a large decrease of their motivation; others do not seem to be much affected, while some report an increase of their motivational orientation (Harter, 1996; Wigfield et al., 2006). Can positive student-teacher relationships be a protective factor in the context of transition from elementary to secondary school? To answer this question, we examined the impact on motivation of the quality of student-teacher relationships in the transition from elementary into secondary school.

Method and data sources

Participants were 1158 French-speaking students from 56 public schools of the Montreal region (Quebec, Canada). Participants completed three times a self-reported questionnaire measuring their achievement motivation (Competence Beliefs, Performance Anxiety, Utility-Value, Interest, and Mastery Goals) and the perceived quality of their relationships with their teachers. Although there are many dimensions to student-teacher relationships, we

focus here on students' perception of the support they receive from their teacher and overall students' perceptions of the quality of student-teacher relationships in their classroom. Times of measurement were at the end of 6th grade (Time 1, last year in elementary school) and at the outset and the end of 7th grade (Time 2 and Time 3, first year in secondary school in Quebec). Participants expressed their opinion on a Likert type scale ranging from 1 (Totally disagree) to 6 (Totally agree). All these scales showed good validity and reliability. Firstly, we calculated a measure of participants' perception of student-teacher relationships by subtracting individual score taken by the end of 7th grade by the score obtained at the end of 6th grade. This new variable was considered continuous in the subsequent analyses, but for the purpose of the figures included in this proposal, we identified four types of student-teacher relationships based on the scores obtained at the times of measurement (25th and 75th percentiles): higher relationships increasing, higher relationships decreasing, lower relationships increasing, lower relationships decreasing. HLM (Bryk & Raudenbush, 1992) was used to model achievement motivation changes according to the evolution of student-teacher relationships and produce latent growth curves. Separate growth models were estimated for competence beliefs, performance anxiety, utility-value, interest, and mastery goals.

Results, Competence Beliefs

As illustrated in Figure 1, in 6th grade participants reporting higher student-teacher relationships also reported higher competence beliefs ($p < .05$) and maintained these kind of relations in 7th grade also maintained higher competence beliefs overtime ($p = .45$). Figure 1

Changes of Students' Competence Beliefs

Performance Anxiety Analyses showed an overall increased of performance anxiety between times of measurement ($p < .05$) Figure 2

Changes of Students' Performance Anxiety Utility-Value Overtime, we observed a decline of utility-value for students reporting a decrease of the quality of their relationships with teachers ($p < .05$) and maintained these kinds of relations in 7th grade also reported higher utility-value overtime ($p < .05$) Figure 3

Changes of Students' Utility-Value Interest Our analyses indicate a significant decline of interest ($p < .05$) and increased in 7th grade ($p < .05$) Figure 4

Changes of Students' Interest Mastery Goals Participants who reported superior student-teacher relationships in 6th grade also reported higher mastery goals ($p < .05$) and increased in 7th grade maintained the same level of mastery goals overtime ($p < .05$) Figure 5

Changes of Students' Mastery Goals Discussion Our results clearly indicate that student-teacher relationships can be a risk factor or a protective factor, depending on students' perception of the quality of these relationships while they transit from elementary to secondary school. Our findings also support Eccles' Stage-environment fit theory according to which secondary school does not allow teenagers to satisfy their psychological needs (Eccles et al., 1993) and highlight the link between attachment, connectedness, and achievement motivation. Finally, our results suggests that transitions themselves are neither good nor bad, what count most is the supportive nature of the environment where the students transit.

The results of the present study could be used to create more developmentally supportive school environments. For example, the size of secondary schools, student-teacher ratio and the number of teachers seen by each student should be minimized. Smaller communities of learners within larger schools building should be created. Measures of personalized follow-ups and tutorials should be installed and the number of activities promoting social connectedness at school should be increased. Instructional practices that keep a group of students with the same teachers for consecutive years (looping) could foster closer connections between teachers and their students should also be considered.

PAPER PRESENTATION

What does "positive school behaviour" mean? Dimensions (not) shared by students and teachers

Valentina Grion, University of Padova, Italy; Rossella Giolo, University of Padua, Italy

Like other European countries, recent Italian school legislation has turned the attention of the education community to the importance of student behaviour in school, and asks for a precise and detailed evaluation of this behaviour. In this light, schools have begun to look for appropriate evaluative tools. During the preliminary phases of creating a behaviour evaluation rubric in a high school, research was carried out with the aim of exploring and identifying the meanings given by teachers and students to the idea of "positive school behaviour", and whether these concepts are shared. Using a mixed method design, researchers have individuated some dimensions of the construct of "positive school behaviour" in teachers and students. Analyses highlight that, in this context, the idea is a construct comprising

dimensions which are not always shared by students and teachers. In this light, there is an emerging need for schools to activate processes of sharing, as a preliminary moment in the behaviour assessment process, and to work towards a "sustainable evaluation".

Over the last few years, the education policies of some of the larger European countries have focused on "school behaviour" and have placed "good conduct" among the necessary requirements for creating effective school contexts that promote student wellbeing. Any action aimed at improving "school behaviour" is considered "a shared responsibility between government, schools and other local partners together with parents and pupils themselves" (Steer, 2009, p. 5). Though later than other European countries, Italy too has recently focused on "school behaviour", within the frame of school reform processes, by issuing some rules aimed at assessing students' school behaviour. Schools have therefore been forced to consider this issue and to construct appropriate assessment instruments. In this context, research on "positive school behaviour" was carried out in a high school in the north of Italy, within a set of activities aimed at building an assessment rubric (Andrade, 2000). A document issued by the English Department for Education and Skills (2005) outlined that, in the school context, the first steps towards improving the wellbeing of its members, are those aimed at sharing consensus on the terminology and its meaning. "It is important to explore popular beliefs and misconceptions that may be held, and secure a whole-school understanding and recognition of the terms' existence and impact" (p. 5).

In the light of these issues, and in the context of the above-mentioned process of building a behaviour assessment rubric, some important research questions have emerged. Researchers are evaluating the following questions: a) what does "positive school behaviour" mean for teachers and students, i.e. what dimensions characterise it? b) if the idea of "positive school behaviour" is shared by teachers and students, does it refer to common dimensions that are considered during the assessment process?

The research took place in a high school specializing in Foreign Languages, Social Sciences and Human Sciences. The participants were 898 students, subdivided in 41 classes from 1st to 5th class, and 101 teachers. All classes and all teachers were involved in the research. The research design was based on the mixed methods design of Tashakkori and Teddlie (2003).

The following research instruments were used:

- a) an open, written question posed individually to each participant, such as: can you outline the main features of a student with "positive school behaviour"?
- b) a Likert scale of "sense of positive school behaviour" with 17 items, each assessed on a scale of four value intervals, to investigate the attitude of participants towards the idea of "positive school behaviour". The items were identified on the basis of their content validity, by a group of experts (15 teachers of different subjects and 2 researchers) who analysed a wide-ranging set of behaviour assessment rubrics.

These materials were collected during in depth research of the documents made available on the Internet by several national and international schools. For each of the two instruments, 825 protocols were collected from students and 31 from teachers. These numbers reflect the school population in the classes in which the research was administered. Given the natural "already given" school context, we have a non-random sample. The research therefore aimed to achieve significant findings from a theoretical-conceptual, rather than a statistical, point of view. By using the SPSS (Statistical Package for the Social Sciences), we submitted the data collected from the Likert-scale instrument to descriptive statistics, a factor analysis and a T-test. Data was submitted to a qualitative content analysis using the Atlas.ti qualitative analysis software. For this kind of analysis, it was decided that not all answers to the open question should be examined, but only a limited number, selected according to a random criterion, in order to decrease the answers to be analysed.

The analysis highlights how, in the specific school context, the idea of "positive school behaviour" refers to a wide range of dimensions, which are not entirely shared by teachers and students. The factor analysis on quantitative data outlined three "macro-dimensions" describing "positive school behaviour": "respect for others and the environment", "participation in school activities" and "school organisation". Among these, the first two are elements of a shared model of "positive school behaviour". As well as these common aspects, the qualitative analyses highlighted, in particular, some heterogeneities between the teachers' model of "positive school behaviour" and that of students. Teachers have a "simple" model, mainly characterised by the 3 macro-dimensions outlined by the factor analysis. Students, on the other hand, show a more complex model which is characterised by a strong sense of personal responsibility as a student, and is described by the following dimensions: a) commitment to good results; b) moral duty of the student as a student; c) caring for peers. If "any assessment act must contribute in some way to learning beyond the immediate task [...] and [it must prepare] students to meet their own future needs" (Boud, 2000, pp.8-9),

the process of building a behaviour assessment rubric described here may make a useful contribution in this perspective. We believe that the project, aimed at acquiring socially shared rules of "positive behaviour", is the result of participants' awareness and co-responsibility, and may represent a possible realisation of what Stobart (2010) defined as "sustainable assessment".

PAPER PRESENTATION

Student perceptions of school climate in an era of reform

Shirley Yates, The Flinders University of South Australia, Australia

Positive relationships between school climate and academic achievement are well established but few studies have examined these relationships at either class or school levels in an era of reform. Two studies were conducted over three and five years, with 309 and 640 elementary and secondary students respectively following the reformation of two schools from single sex to coeducation. Students' perceptions of the climate of their coeducational classrooms were measured annually in Study 1 and of the school in Study 2, with both studies using the same academic achievement measure. Statistically significant increases in student achievement following the introduction of coeducation were evident in both studies. In Study 1 boys perceived their coeducational classrooms to be significantly more Personalized. In Study 2, girls perceived less friction, were more cohesive and satisfied with life in the coeducational school than boys. However, once the hierarchical nature of the data was taken into account, only satisfaction with school life related directly to academic achievement for cohort and grade groups, with more satisfied cohorts making better progress over time. The measures of teacher personalisation at the classroom level and satisfaction at the school level are both derived from Moos (1974) Relationship Dimensions and relate to students' experiences of the nature and intensity of personal relationships in the environment. Results from these two studies indicate students' experiences of coeducational relationships extended beyond the classroom door to the wider school environment and were related positively to increases in achievement. These findings have implications for policy and practice.

Students' perceptions of the school climate were measured with My School Inventory (MSI), adapted from My Class Inventory (Fisher & Fraser, 1981; Fraser, Anderson & Walberg, 1982) or School Learning Environment Inventory (SLEI), adapted from the Learning Environment Inventory (Anderson & Walberg, 1974; Fraser et al., 1982).

Academic achievement in Studies 1 and 2

Academic achievement was measured with Word Knowledge Test 1 (WK1), Test 2 (WK2) or Test 3 (WK3) (Thorndike, 1973). Each test contains 40 word pairs, rated as the same or opposite in meaning.

Procedure

Study 1 was conducted annually over 3 years (Times 1, 2 & 3) (T1, T2 & T3) before during and after the introduction of coeducation. Study 2 was conducted annually over 5 years (Times 1, 2, 3, 4 & 5) (T1, T2, T3, T4 & T5), with coeducation introduced at T1 for secondary students and T2 for elementary students. All questionnaires and WK tests were administered to students in their classrooms with WK1 administered to Grades 3-7, WK2 to Grades 8-10 and WK3 to Grades 11-d 12. All students in Study 1 completed the ICEQ. In Study 2, Grades 3-9 were administered MSI, with SLEI given to Grades 8-12.

Findings

Statistically significant increases in student achievement over time were evident in both studies. An ANOVA in Study 1 revealed that overall, there was a significant increase in Personalization from T1 to T2 (paired t (308) = 3.96, p Participation, Independence, Investigation and Differentiation scales between T1, T2 and T3. While gender was not a significant direct factor in student educational achievement in Study 2, structural equation modelling analyses revealed that over the five years following the introduction of coeducation, the girls were more cohesive, satisfied with life in the CE school and perceived less friction than boys. However, once the hierarchical nature of the data was taken into account with Hierarchical Linear Modelling, only satisfaction with school life was related directly to academic achievement for cohort and grade groups, with more satisfied cohorts making better progress over time.

Educational significance of the research

The last forty years have witnessed an unprecedented number of reforms of single sex schools but despite the pervasiveness of these reforms and the profound changes they have brought to the school life experiences of countless numbers of students in several countries, the reforms have passed almost without notice. In her discussion of the numerous school reforms in England Sutherland (1985, p 155) noted there must be few instances where such a radical change in education has occurred in such an absent-minded way and further what remains regrettable is that

changes in educational organization take place without monitoring to judge their effects (Sutherland, 1985, p 161). Results from these two studies indicate the major organisational change from single sex to coeducation in the two schools did have an effect on relationships between student achievement and experiences of the Relationship Dimensions of life at classroom and school levels. In the coeducational classroom boys perceived greater opportunities to interact with their teacher and of his/her concern for their personal welfare and social growth. At the school level students increased satisfied with life in the coeducational school was related to increased achievement. Taken together, evidence from these two studies extends the well established relationship between students' experiences of school life and achievement (Cohen et al. 2009) to include eras of organisational change but also lends support for the argument that a return to single sex classrooms and schools is contraindicated, at least for boys. Further research into the effects of group level factors on school climate is required for boys and girls at elementary and secondary school levels in single sex and coeducational settings.

PAPER PRESENTATION

What matters at school? The Finnish pupils' perceived competence, belonging and well-being

Janne Pietarinen, University of Eastern Finland, Finland; Kirsi Pyhalto, Helsinki University, Finland; Tiina Soini, University of Tampere, Finland

Research on pedagogical practices have shown that pupils' sense of competence, belonging and experienced well-being are the crucial preconditions for pupils' learning, academic mastery in school and success in their future educational track. In this paper we are focusing on exploring how the pupils' self-reported competence is regulated by their sense of belonging and well-being in the school community.

Altogether, 170 pupils (91 fifth and 79 seventh graders) from three case schools responded to the survey. The total response rate was 95%. BCW questionnaire was developed by authors and it embodied 39 statements about different aspects of belonging including two complementary scales, the peer group scale and 2) teacher-pupil interaction scale, competence consisting of statements about perceived competence in studying, academic achievement and assignments given by the teachers and well-being.

A stepwise regression analysis showed that both pupils' perceived well-being and teacher-pupils interaction predicted the pupils' academic competence [$F(2,167)=128,2$, $p=.000$, $\text{Adj-}R^3=.601$]. However, the relation between perceived belonging in peer group and academic competence did not exist in this regression model. The results pointed out that pupils' commitment and persistence in studies are regulated by the perceived fit between the pupil's capacity to manage their own learning and teachers' expectations about the pupils' resources to cope with multiple and parallel learning tasks and -contents.

Introduction

School is a central developmental context for pupils (Eccles 2004). School provides various opportunities for pupils learning, growth and well-being. Pupils also evaluate and monitor their success in coping with social, cognitive and emotional challenges set by the school (Anderson et al., 2000). Research on pedagogical practices have shown that pupils' sense of competence, belonging and experienced well-being are the crucial preconditions for pupils' learning, academic mastery in school and success in their future educational track (Deci & Ryan, 2002; Midgley & Edelin, 1998; Ryan & Deci, 2001; Pyhältö, Soini, & Pietarinen 2010). Coherent, meaningful and functional perceptions of school's pedagogical and social activities are likely to facilitate pupil's capacity for intentional and responsible management of new learning, both at an individual and community level. Yet, little is known about how pupils themselves experience the school in terms of interaction with teachers and peer group, well-being and studying. This study focuses on exploring the interrelation between perceived competence as a student, experienced well-being and sense of belonging to the school community. The study is a part of a larger national research project on learning and well-being in comprehensive school (2004 - 2014).

Aims

This study aims to gain better understanding about the preconditions that may lead to pupils' commitment and persistence in studies. More specific, in this paper we are focusing on exploring how the pupils' self-reported competence is regulated by their sense of belonging and well-being in the school community. Our hypothesis is that a precondition for meaningful learning and experienced competence as a student is that pedagogical practices of school promote pupils' sense of belonging and experienced well-being.

Methods and analysis

Altogether, 170 pupils (91 fifth and 79 seventh graders; 55% girls and 45% boys) from three case schools responded to the survey. The criteria for selecting the fifth and seventh graders were that primary-secondary school sift have found to provide significant challenges and opportunities for pupils' learning, well-being and social relations at school (Pyhältö, Soini & Pietarinen, 2010; Pietarinen, Pyhältö & Soini, 2010). The total response rate was 95%. The data presented here is a part of (first measurement) the longitudinal research design that focuses on exploring pupils' learning and well-being in educational transitions.

BCW questionnaire was developed by Pyhältö, Pietarinen & Soini and it embodied 39 statements about different aspects of belonging including two complementary scales, 1) the peer group scale and 2) teacher-pupil interaction scale, competence consisting of statements about perceived competence in studying, academic achievement and assignments given by the teachers and well-being measured using a modified and complemented versions of exhaustion scale (Maslach & Jackson, 1981) and anxiety and lack of interest scales (Mäkinen et al., 2004) as well as school burnout scale developed by Salmela-Aro et al. (2009). Pupils rated all the items on a 5-point scale (1 strongly disagree; 5 strongly agree).

Statistical analyses included the reliability analysis of the BCW sub-scales and regression analysis. First, the internal consistency of sub-scales was calculated with Cronbach's α for direct sums of items. After this, a stepwise regression analysis was carried out to investigate to what extent perceived well-being and sense of belonging in peer group and in teacher-pupil interaction influenced pupils' perceived competence as a student.

Results

The reliability analysis showed that consistency of the sub-scales was sufficient. The items related to pupils' perceived competence ($\alpha=.84$, 6 items), experienced belonging to peer group ($\alpha=.73$, 5 items) and with pupil-teacher interaction ($\alpha=.84$, 8 items) and well-being ($\alpha=.84$, 6 items) made possible to form adequate sum variables for the further analysis. A stepwise regression analysis showed that both pupils' perceived well-being and teacher-pupils interaction predicted the pupils' academic competence [$F(2,167)=128,2$, $p=.000$, $\text{Adj-}R^2=.601$]. More specific, experienced burdening including lack of interest, inadequacy at school and cynicism predicted pupils' decreased sense of competence at school. In addition, the regression model confirmed that experienced belonging in the pupil-teacher relationships seems to reinforce the pupils' capacity to regulate their learning and develop their participatory skills at school's multiple social environments. Pupils especially valued teacher's expertise in teaching, dialog with teachers, constructive feedback, fairness and emotional support received in pupil-teacher relationship. However, the relation between perceived belonging in peer group and academic competence did not exist in this regression model.

Discussion

The results pointed out that pupils' commitment and persistence in studies are regulated by the perceived fit between the pupil's capacity to manage their own learning and teachers' expectations about the pupils' resources to cope with multiple and parallel learning tasks and -contents. Hence the findings suggested that, pupils' sense of competence is a relational phenomenon that is clearly connected with sense of belonging with teachers, but not directly to the peer group interaction. A reason why peer interaction was not included in the model may be that the influence of peer group interaction on the perceived competence is indirect and mediated by other constructs (Pyhältö, Soini & Pietarinen, 2010). Finally, results showed that promoting pupils meaningful learning, commitment and persistence in studies are highly dependent on the quality of interaction in teaching-learning processes and more broadly pedagogical practices adopted by the teachers in school's everyday life.

PAPER PRESENTATION

Can Grades in a Teacher Preparation Program Predict Teacher Effectiveness?

Stelios Orphanos, Frederick University, Cyprus

Teachers are highly influential to student achievement and researchers have been trying to identify the teacher characteristics most predictive of student achievement. This study explores the relationship between teachers' academic performance during pre-service preparation and future teacher effectiveness. The main research hypothesis is that controlling for measures of teacher quality and school context teachers' academic performance has a positive effect on teacher effectiveness.

The sample includes 229 elementary school teachers in Cyprus. Surveys administered to teachers, principals and parents provided information on teacher effectiveness, teaching practices and contextual factors. Teachers' transcripts provide grades in education courses taken and were matched to teacher survey data. Teachers were rated by principals and parents on nine dimensions of teacher effectiveness.

Structural equation modeling techniques were used during data analysis. Controlling for teacher experience, advanced degrees and contextual factors, teachers' grades are a significant predictor of teachers' effectiveness. One st.dev increase in academic performance is associated with a 0.678 st.dev increase in teachers' effectiveness as measured by the average effectiveness rating. Also, better grades are positively associated with teachers putting forth more effort, using innovative assessment methods more frequently and more preparation time.

The results show that teachers' grades can be linked to teacher quality and effectiveness. Teachers' grades partially reflect demonstrated knowledge and skills that seem related to subsequent teacher effectiveness. Finally, the context of teaching plays an important role in determining the nature of the relationship between teachers' academic performance and effectiveness.

1. Objectives

Can teacher effectiveness be predicted? Teachers are highly influential to student achievement therefore researchers have been trying to identify the teacher characteristics most predictive of student achievement. In this study, I examine whether teachers' academic performance during pre-service preparation can predict teacher effectiveness.

The research questions are the following:

What is the contribution of teachers' academic performance during pre-service preparation to teacher effectiveness controlling for personal teacher characteristics and contextual factors (teacher collaboration, principal's instructional leadership)?

Which component of teachers' academic performance during pre-service preparation matters the most to teacher effectiveness?

What is the relationship between teachers' academic performance during pre-service preparation and teachers' use of effective teaching practices?

2. Theoretical framework

The study postulates that teachers' academic performance (measured by grades in four areas of teacher preparation curriculum), measures of teacher quality (experience, advanced degrees) and context (school leadership, teacher collaboration) have a direct and an indirect (through teaching practices) effect on teacher effectiveness. It is hypothesized that teachers' academic performance has a positive direct influence on the use of effective teaching practices and on teacher effectiveness. It is also hypothesized that teaching experience, advanced degrees and the context of teaching positively influence teacher effectiveness.

A number of researchers support the development of multiple data sources in teacher evaluation because multiple measures are more likely to yield fair teacher evaluations (DiPaola & Stronge, 2003). In this study, I use multiple teacher ratings collected from school principals, parents and teachers as indicators of teacher effectiveness.

3. Methods

This study utilized a cross-sectional survey design. The sample includes 229 elementary school teachers who are graduates of the same preparation program in Cyprus. Surveys administered to teachers, school principals and parents provide information on teacher effectiveness, teaching practices and contextual factors. Teachers' transcripts provide grades in education courses taken in various content areas and were matched to teacher survey data. Teachers were rated (on a scale of 1-10) by principals and parents on nine dimensions of teaching effectiveness (examples include level of preparation, classroom management, ability to improve student achievement etc).

Structural equation modeling techniques were used to investigate the relationship between academic performance and teacher effectiveness. Appropriate measurement models for latent variables were constructed and two SEM models with two outcome variables (teachers' absolute overall effectiveness rating and teachers' relative ranking within schools) were estimated.

4. Results and conclusions

Table 1 shows the results of the SEM analysis. Controlling for teacher experience, advanced degrees and contextual factors, teachers' grades are a significant predictor of teachers' effectiveness. One st.dev increase in academic

performance is associated with a 0.678 st.dev increase in teachers' effectiveness as measured by the average effectiveness rating.

All four components of teachers' academic performance are positively associated with teacher effectiveness. Teachers' GPA in pedagogy has the strongest effect and GPA in practice teaching has the smallest -but still substantial- effect on teacher effectiveness. In addition, academic performance is positively related to teachers' relative ranking within schools. Collectively, these results support the positive association between GPA in education coursework and teacher effectiveness reported in earlier studies (Ferguson & Womack, 1993; Guyton & Farokhi, 1987; Nelson & Wood, 1985).

Table 2 shows the effects of teachers' academic performance on the use of effective teaching practices.

Better grades are positively associated with teachers putting forth more effort in their work, using innovative assessment methods more frequently, involving parents and spending more time on daily planning and preparation. Also, teachers with better grades believe that teachers and not students' background has the greatest influence on student achievement.

Several conclusions emerge from these results. First, grades can be linked to teacher quality and effectiveness. Crude measures of teacher quality such as degrees, amount of coursework or certification status, used in previous research, may be not be the right variables to use. Second, knowledge demonstrated in education coursework is relevant to teacher effectiveness. Teachers' grades partially reflect demonstrated knowledge and skills that, according to the results, are related to subsequent teacher effectiveness. Third, the context of teaching plays an important role in determining the nature of the relationship between teacher quality and effectiveness. Simply providing teachers with coursework and opportunities to act on what they learn may not be enough unless the right political and educational context is in place.

6. Scientific and scholarly importance

The title of the paper asks if teacher effectiveness can be predicted. Results show that, at least in Cyprus, teachers' undergraduate academic performance may be used to predict teacher effectiveness. The analysis shows that it is more likely for teachers with a high GPA to receive higher effectiveness ratings from the school principal and parents. The study is important for two more reasons. First, it is the first study in Cyprus to explore the relationship between teachers' academic performance and teacher effectiveness. In addition, similar studies outside the USA are rare. Second, this is the first study that combines the use of teachers' grades and three different teacher ratings in exploring the relationship between teachers' academic performance and teacher effectiveness.

PAPER PRESENTATION

Fostering counseling competence of pre-service teachers

Silke Hertel, German Institute for Internat.Educational Resarch, Germany; Johannes Naumann, Geman Institute for International Educational Research, Germany; Bernhard Schmitz, Technical University of Darmstadt, Germany

Recent conceptions of teacher professionalism include counseling knowledge in what is seen as a core set of teachers' professional competencies (e.g. Baumert & Kunter, 2006), but an explicit training of counseling skills is rarely included in teacher education. Until now there are no findings whether pre-service teachers can already acquire counseling competence during their courses of study at university. Within the scope of this study it was examined, whether - and if so - which aspects of the counseling competence can already be acquired by pre-service teachers. Following Hertel (2009) five di-mensions of counseling competence were distinguished: personal resources, social co-operation, counseling skills and pedagogical knowledge, solution and process orienta-tion, and coping. The participating pre-service teachers (N=40) were enrolled in teacher education programs at the university. The study is based on a quasi-experimental design, participants in the experimental group were trained in counseling skills, partici-pants in the

control group received training on teachers' general pedagogical knowledge. Self-ratings and knowledge tests were applied to assess participants' competence gain in a multi-method-fashion. MANOVAs and ANOVAs were conducted to analyze the data. The results show that pre-service teachers can acquire specific aspects of counseling competence already in their university education. Concluding from that, training of counseling skills should be included in (pre-service) teacher education. Additional research for the development of counseling competence in a teacher's career is necessary to better adjust the interventions to the needs of (pre-service) teachers.

Scientific issue

Teachers' professional responsibilities are constantly changing in a world where education is an increasingly important resource. Parents demand teachers' advice how to support their children at home (e.g. Cooper, Lindsay & Nye, 2000; Trautwein & Ludtke, 2009). Positive effects of a frequent parent-teacher-communication and teachers' counseling activities are well documented (e.g. Lengua & McMahon, 2000; Manz, Fantuzzo & Power, 2004). In line with this, recent conceptions of teacher professionalism include counseling knowledge in what is seen as a core set of teachers' professional competencies (e.g. Baumert & Kunter, 2006), but an explicit training of counseling skills is rarely included in teacher education. Until now there are no findings whether pre-service teachers can already acquire counseling competence during their courses of study at university. Within the scope of this study it was examined, whether - and if so - which aspects of the counseling competence can already be acquired by pre-service teachers.

Theoretical and empirical background

In the latest conceptions of teacher professionalism counseling competences are explicitly specified within the core set of teachers' professional competences (e.g. Baumert & Kunter, 2006; Terhart, 2002). According to Hertel (2009) five dimensions of counseling competence can be distinguished: personal resources, social co-operation, counseling skills and pedagogical knowledge, solution and process orientation, and coping. Frequently, teachers perceive their relations to parents as an extremely difficult part of their job, and as a major source of job dissatisfaction (Vickers & Minke, 1995). Also, when teachers are not educated in counseling tasks, they are likely to develop attitudes and professional beliefs that do not endorse the importance of counseling as part of their job (e.g. Wild, 2003). Teachers' professional beliefs, in turn, are known to have a major influence on teacher practice (e.g. Deemer, 2004; Hoy, Davis & Pape, 2006; Pajares, 1992). In particular, teachers' professional beliefs predict behaviors relating to counseling tasks, such as the arrangement of learning environments, promoting students' motivation, and responding to special learning needs (Ozgun-Koca & Sen, 2006; Hall, 2005; Richardson, 1996). Counseling talks are an important starting point for an intensive collaboration with parents and therefore they provide an individual support for pupils. Many studies were able to indicate positive effects of the collaboration of teachers and parents for the performance and the school achievement of pupils (e.g. Epstein, 1991; Arunkumar, Midgley & Urdan, 1999; Lengua & McMahon 2000; Wild, 2003).

Applied empirical research methodology

Within the scope of a quasi-experimental experimental-control-group-design with a pre-post test, the effectiveness of an intervention, developed to support the counseling competence, was investigated. Participants were N=40 students enrolled in a teacher trainee program at university. Students in the experimental group visited a counseling competence seminar; students in the control group visited a seminar on teachers' general pedagogical knowledge. For the pre- and posttest, self-ratings of perceived counseling competence were collected. Although subjective in nature, self-ratings have been shown to validly tap on participants' factual abilities in a number of areas, such as inter-cultural skills (Ward, Fisher, Lam, & Hall, 2009), creativity (Kreitler & Casakin, 2009), computer skills (Ballantine, Larres, & Oyerle, 2007), counseling (First Author, 2009), and even personnel selection (Randall, Ferguson, & Patterson, 2000). Also, meta-analytic results indicate the validity of self-reports of abilities, especially under circumstances as given in this study, such as confidential treatment of the data, or subjects knowing that some objective measure would be collected in addition to the self-reports (Mabe & West, 1982). Participants were asked to rate their counseling competence (e.g. self-reflection, communication-skills, coping competence) on six-point rating scales. These measures were combined into an over-all measure of perceived counseling competence. Cronbach's α for this measure was .77. Participants' counseling knowledge was assessed with a four-item declarative knowledge test covering topics that were addressed in the training. The training was part of the regular semester and consisted of 13 sessions of 90 minutes. The main topics addressed were communication theory, communication strategies and self-regulated learning theory. The communication strategies were trained in role-plays. Four parent-teacher counseling talks with realistic scenarios were simulated in the course of the training. Knowledge about processes of learning in general and learning strategies in particular were covered by introducing a model of self-regulated learning (Schmitz & Wiese, 2006). This model included learning strategies and supportive strategies that teachers could use in counseling tasks. Multivariate and univariate ANOVAs were conducted to analyze the collected data.

Research results

The analyses prove statistically significant interactions of time by treatment for the competence dimension “personal resources” [$F(1,21)=5.6$, $p<.05$, $Eta^2=.21$] and the counseling knowledge [$F(1,21)=4.5$, $p<.05$, $Eta^2=.18$]. For students in the experimental group an increase in these competence aspects was observed. Statistically significant differences between the control group and the experimental group also appear in the area of “the perceived increase in competence” [$F(1,38)=18.2$, $p<.01$, $Eta^2=.32$] and “the self-efficacy in relation to counseling talks” [$F(1,20)=5.5$, $p<.05$, $Eta^2=.22$]. As expected, higher values for the participants under experimental condition were observed on these scales.

Theoretical and practical conclusions

Already within the scope of university education, pre-service teachers can acquire counseling knowledge and counseling competence. Thus, already from the present results, but even more given that they might be replicated and extended, there is good reason to give increased attention to teachers’ competence in parent counseling and include respective trainings both in their primary education, and on the job. Additional research for the development of counseling competence in a teacher’s career is necessary to better adjust the interventions to the needs of (pre-service) teachers.

PAPER PRESENTATION

Understanding teachers as learners: a postmodern reading of current explanations.

Aileen Kennedy, University of Strathclyde, United Kingdom

At the heart of this paper is a desire to use theoretical insights derived from postmodern thinking to practical advantage in the consideration of how teacher professional learning can be supported. It starts from the premise that teachers’ dispositions towards their own learning are not fixed, rather they are dynamic, contingent and responsive to experience, environment, personal lives and professional demands.

It is argued that existing literature on teacher professional learning is epistemologically narrow, relating most commonly to notions of managerialism and effectiveness. This argument put forth in this paper draws on postmodern thinking in analysing the possibilities and multiple interpretations of existing literature on teacher professional learning, taking into account writing on teacher development theory, empirical research into career-stage CPD needs and the growing body of literature which advocate a more socially-situated view of teacher learning. It also draws on career development theory, in particular the notion of employees’ ‘psychological contracts’ with their employers, in coming to a conclusion that a much wider and dynamic conception of teachers’ ‘needs’ is necessary.

At the heart of this paper is a desire to use the theoretical insights derived from postmodern thinking to practical advantage in the consideration of how teacher professional learning can be supported.

The understanding of teacher professional learning that I develop in the paper draws on postmodern thinking which rejects the notion that situations can be explained by grand narratives or theories (Lyotard, 1984), and rather seeks to interpret and reinterpret situations from a range of different perspectives. Inherent in this argument is an explicit attempt to expose power, or what Foucault would call ‘regimes of truth’; the dominant discourse which shapes acceptability of what is deemed to be ‘truth’. It is important, however, to ensure that such theoretical discussions are used to inform thinking about policy and practice, and do not to serve to disconnect them further. In this regard, I consider a range of contemporary literature on teacher professional learning, with a view to identifying and exposing the epistemological assumptions on which they are based. In doing this, it is hoped that a wider, more nuanced view of teacher learning can be promoted as a challenge to the dominant view which in effect limits understanding of teacher professional learning to a series of standards, frameworks and career stages in order to allow for ‘effective management’.

Early attempts to classify stages of teacher development, e.g. Dreyfus & Dreyfus (1986) have been discredited for their linear and narrow focus, with more recent attempts paying more attention to the importance of context (Huberman, 1993; Day et al., 2007; Fraser et al., 2007). However, even the most recent, research-informed attempts at explaining how teachers learn across the career course remain partial and inadequate for the purposes of supporting meaningful, career-long professional learning. At the root of this, I argue, is the obvious, yet often overlooked fact that teachers are human beings, with complex and unique life experiences, histories, values, expectations and aspirations, which change and develop as they interact with the world. In essence, teachers are dynamic beings and cannot easily be captured by static, neatly defined categories.

In much of the literature focusing on teacher professional learning, the notion of 'career stage' is used in a relatively uncritical way, generally suggesting post or role-related stages in a teacher's professional life. There is a plethora of studies, often Government-funded, which seek to uncover lists of 'CPD needs' that can be associated with teachers at particular career stages (Kennedy et al., 2008; Karstanje & Webber, 2008; Woods et al., 2009;). The rationale behind this is usually that identifying teachers' perceived needs will allow CPD provision to be more appropriately organised. The paper challenges this, suggesting that the answers to the questions asked in such research are usually framed within dominant discourses which stop teachers even considering alternatives to role-focused CPD which is 'provided by the employer.

A growing body of literature on professional development has coined terms such as 'professional evolution' (Huberman, 1993) and 'professional life phase' (Day et al., 2007) which convey a more socially-situated conception of teacher career stages relating to both professional and personal influences which go beyond consideration of mere occupational preparation for a specific role. These explanations, while helpful, are still limited by their attempts to categorise teachers within certain parameters and to associate these parameters with particular CPD needs. The complexities of workers' engagement with their professional learning is an area of investigation which has long been considered in career development research, albeit not specifically in relation to school teaching, and it is to this body of literature that I look to seek ways of understanding the complexities of teachers' attitudes to their own professional learning, and ultimately to help inform policy and practice in supporting teacher professional learning by advocating alternative views of thinking about processes.

Interestingly, literature on teacher professional learning seems to inhabit a separate world from general career development theory. In career development theory, the term 'career development' is subject to debate and reinterpretation, mirroring the developments in literature on teacher development which has moved from an occupationally focused and very linear construction of development to a more socially-constructed, complex one where factors wider than the immediate employment situation are acknowledged as influential. However, many career development theorists argue that it is not simply our growing understanding of the wider personal and social influences that have forced new areas of exploration, but also a sociological change in the way that careers are configured, experienced and lived; something that appears to have been sidelined in literature on teachers and teaching. Amundson, Parker & Arthur (2002) describe the experience of contemporary career development as one of 'continuing tensions between leveraging past experience and positioning for future opportunity' (p. 27). And Patton & McMahon (2006) argue that workers, especially younger workers, now have to focus on 'employability rather than job security' (p. 6), in a world where most workers will change career at some point in their lives. Patton & McMahon (ibid.) go on to outline a number of emerging ways of conceiving career development, concluding that key elements of any definition would attend to 'the individual, the environment, interaction and change' (p. 7), thereby acknowledging the dynamic nature of career development.

Hess & Jepson (2009) point to the growing need for research which attempts to 'define the twenty-first century employment relationship' (p. 261) which they argue has changed as a result of 'an increasing number of older workers alongside younger workers in organizations with flatter structures' (ibid.). They focus on the concept of the 'psychological contract' which is an implicit understanding between an employer and an employee of the extent and parameters of their respective responsibilities and commitments to each other. If the employer is seen to have compromised their side of the PC, the workers' engagement is likely to decrease, and conversely, if employers are perceived to have kept their end of the contract then employees are more likely to report job satisfaction and to be prepared to 'go the extra mile' (Shen, 2010), which includes engagement in furthering professional learning. This provides another interesting, yet overlooked lens through which to explore teacher disposition towards professional learning.

In conclusion, the paper offers a range of perspectives on teacher professional learning, all of which are deserving of consideration in both theoretical and practical senses, and which go some way towards deepening understanding of the complexities of teachers' engagement with professional learning.

PAPER PRESENTATION

Sharing Data in International Research – A Theoretical Discussion on Pros, Cons, and Solutions

Eveline Gutzwiller-Helfenfinger, The Institute of Pedagogical Professionalism and School Culture, Switzerland; Anna Tapola, Linnaeus University, Sweden

International, collaborative, and comparative research is often viewed in very positive terms, as being especially powerful or fruitful regarding its outcomes, not least in terms of education for a global networked society (EGNS). However, such research endeavours are not unproblematic. This paper aims to identify and discuss potential advantages and difficulties of sharing data in international research projects, for example The Linnaeus Project (TLP)

but also other research initiatives on EGNS. Additionally, we suggest solutions to how the difficulties can be overcome. One of the issues concerns the very nature of data (e.g. interviews) collected by a project partner, which will also be analysed by researchers in other national groups. Since the data are embedded in a specific national context, and might also be presented in a language which is not the analysts' mother tongue, such data sharing needs to be carefully prepared. For example, the translation of transcripts goes beyond simply transferring utterances from one language into another; the translation needs to be sensitive to contextual aspects, and the analyst needs to be very familiar with the contextual circumstances of the initial data collection. Another option might be to analyse all data in the original language only, thereby making translation unnecessary. This means that a specific national partner project needs to include members who are familiar with other national contexts, including the original language. Although these issues are discussed in the context of TLP, they are highly relevant to other projects, especially in terms of research on EGNS.

Aim

This paper aims to identify and discuss potential advantages and difficulties of sharing data in international research projects, for example, the Linnaeus Project, or other research initiatives on education for a global networked society (EGNS). The paper also aims to provide solutions to how difficulties can be solved. Research Questions1. What potential advantages can be identified with respect to data sharing in an international research project?2. What potential difficulties can be identified with respect to data sharing in an international research project?3. How can potential difficulties be prevented or solved? The problem and its relevance to international research within EARLI International, collaborative, and comparative research is often thought of in very positive terms. It is considered as being especially powerful or fruitful regarding outcomes, not least in terms of EGNS. Thus, covering more than one national and cultural context and being able to include different educational systems enable researchers to study more closely various conditions and contexts of teaching and learning. However, such research also involves a number of difficulties that must be addressed: Dealing with different languages, geographical distances, and differing settings and infrastructure are some of the very basic difficulties involved. The issue of data sharing is very prominent, because accessing and using data generated by several project partners is one of the core activities of international collaborative research. Several domains can be identified within the issue of data sharing, e.g., the legal context (Fitzgerald & Pappalardo, 2007); infrastructure planning and data curatorial responsibilities (Ruusalepp, 2008); data accessibility and safety (Axelsson & Schroeder, 2009); and representation format (Makedon, Steinberg, Rahme, Tzika, Wishart, & Wang, 2003). The topic addressed in the present paper is the representation format of data, and includes both the mode of representation (e.g., verbal or visual) and the language used. Successful data sharing is the basis for subsequent analyses and enables researchers to gain new and important insights. Accordingly, research within EGNS investigating the influence of the globalization of education is dependent on accessible, useable, and highly qualitative national and international data. The Linnaeus Project represents one such international research project within EGNS, and will be used as an example to identify and discuss potential advantages and difficulties of sharing data in international research projects.

Context

The Linnaeus Project is a new international research initiative, which currently includes seven national groups and 25 European researchers. The Linnaeus Project as a whole aims to analyse the preconditions for integrative approaches in teacher education that integrate morality, democratic aspects, and subject matter into new entirities. Its focus lies on contemporary challenges against humanity and human living conditions.

Pragmatic grounding

The topic addressed in this paper has a clear pragmatic grounding; investigating advantages, difficulties as well as potential solutions to the difficulties encountered in international, collaborative, and comparative research projects. Accordingly, the paper especially deals with how successful international research collaboration aims to gain new and important insights in the field of EGNS. The basic idea of data sharing promoted here states that it is beneficial for national groups to have access to data from other national groups as well, particularly within comparative studies. When data collected by a project partner will also be analysed by researchers in other national groups, questions of safe data storage, data accessibility, data format, etc. arise. Since the data are embedded in a specific local and national context, it is possible that they are rendered in a language other than the analysts' mother tongue. Consequently, this language difficulty must be overcome. One possible option might be to translate the data. In this case, the translation needs to be sensitive to contextual aspects, and the analyst needs to be very familiar with the contextual circumstances referred to the initial data collection. Translation may be a good option for verbal data derived from questionnaires, especially if mainly closed (as compared to open-ended) questions are used. In the case of interview data, high-quality, context sensitive translations may be required, and the costs for such translations

must be included in the research budget. Another option might be to analyse all data in the original language only. This means that a specific national partner project interested in the (foreign language) data needs to recruit members who are very familiar with other national contexts, including the original language, and have the necessary analytic skills. These researchers will then have to collaborate with the project partner who collected the data and analyse the data in the original language.

Conclusions

Collaborative international research projects must consider the nature of the data to be shared, especially their representation format. Since national research groups often differ with regard to language, both data collection and analysis are affected by the difficulty of coordinating different languages. Accordingly, researchers must decide whether data will be translated into their national language and then analysed or analysed in another language by a skilled member of the research team. Both options require careful planning and are accompanied by specific costs, which in turn must be included in the research budget.

PAPER PRESENTATION

Relative Judgment of Graphics in the Interpretation of Meaning

Robert Danielson, California State University, Chico, United States; Neil Schwartz, California State University, United States; Jessica Stanley, California State University, Chico, United States; Sevil Gonen, California State University, Chico, United States; Erica de Vries, Universite Pierre-Mendes-France, France

Previous research has shown that humans often make judgments in relation to the context surrounding them. This context may either be internal representations of previous knowledge (eg. about prices of items or previous self-history), or may be in reference to previously or concurrently presented visual stimuli. The present study highlights these referential effects on judgments specifically related to visual media. Graphics were presented in one of two ways; with one definition and other graphics as the reference, or alone with multiple definitions as references. Results suggest that when participants are presented with one definition and asked to rate multiple graphics on the definition-graphic correspondence, the graphic which matches the definition is rated as more similar compared to the same graphic when judged against multiple definitions. The findings are discussed in the context of frames and the theory of rationale choice relative to learners' interpretation of the graphics they view when accompanying text.

Aims

Previous research has shown that when humans make judgments of presented stimuli, they often do so in the context of other stimuli. Whether it is the case that buyers are referencing prices presented with internal prices derived from experience (Yadav & Seiders, 1998) demand for items when scarcity and previous demand are presented (Worchel & Adewole, 1975); or judgments of subjective happiness in reference to previous life experiences (Parducci, 1995) the context of the judgment is just as important as the judgment itself. This phenomenon bears relevance to the judgments learners make when interpreting the visualizations that accompany text.

Tversky, & Kahneman (1981) found that when presented with identical survival ratios, the framing of the ratio (1/3 will live vs 2/3 will die) had a significant effect on the decision individuals made. Tversky (2004) contends that "when presented with two stimuli, the variant is more similar to the prototype than vice versa". This is clarified by the statement "an ellipse is more similar to a circle than a circle is to an ellipse" (Tversky, 2004). We suggest that the same types of judgments are made by learners when they attempt judgments about the relation between visualizations and

the conceptual content of text. For example, learners may view abstract visualization as more concrete, but concrete stimuli will not be seen as more abstract.

Previous research has focused on the degree to which graphics have influenced learning when paired with text. Schnotz & Bannert (2003) have demonstrated that unique graphics, paired with identical texts, create different mental representations of the textual information, and poorly selected graphics interfere with mental model construction. Thematic graphics have been found to influence a learner's cognitive interaction with a passage (Schwartz, Battinich, Lieb & Mortensen, 2008; Schwartz, Lieb, Battinich & Kuinke, 2007), and can increase recall of both literal details as well as deeper level themes (Mortensen & Schwartz, 2009).

Yet, Tversky & Kahneman (1981) found that when participants were asked to make specific decision about problems, the framing of the question could change the outcome of the answer. We expect the framing effect to operate with visual stimuli as well. Thus, in the present investigation, we examined two specific ways to understand if a thematically related graphic would be interpreted differently based on the contextual frame in which learners' were asked to make a choice about meaning. We expected that if frame theory operates to influence learners' interpretive choice about graphics, then the graphics learners view are prone to contextual relativity. That is, a graphic, when paired with multiple definitions, should be evaluated differently than multiple graphics evaluated against a single definition. If the interpretation of graphics is contextually independent and distinct—and immune to interpretive relativity—then judgments of meaning should be immutable given variations of correspondence.

Methods

Design

Two factors, Presentation Format and Graphic Metaphor were crossed to yield 6 experimental cells. The resulting design was a 2 Presentation Format (Multiple Graphics vs. Multiple Definitions) by 3 Graphic Metaphor (Civil War vs. Genocide vs. Geographic Location) ANOVA.

Participants

Participants were 99 undergraduate volunteers randomly assigned to the experimental groups.

Materials

Experimental graphics. Three metaphorical graphics were designed. The first graphic was a topographical representation of a region. The second was a graphic depicting the concept of Civil War and shown with two lions of similar color and size engaged in combat. The third graphic depicted the concept of Genocide and consisted of two lions of similar color and size devouring a third lion of a dissimilar color and size.

Experimental Website. An experimental website was created to convey the experimental materials. This website contained 6 hypermedia pages displaying the definitions and graphics, as well as a routing page designed to assign participants into one of two conditions.

Procedure

Participants navigated through an experimental website where they were routed into one of two conditions. In condition one, participants were presented with the definition of genocide. They were then presented with all three metaphorical graphics. In condition two, participants were presented with the definition of genocide, civil war, and geographic location. They were then shown the metaphorical graphic depicting genocide. Their task was to determine if the graphics corresponded well to the definition by rating the correspondence on a scale from one to five.

Findings

Preliminary results revealed an interaction between Presentation Type (Multiple Graphics, Multiple Definitions) and Graphic Metaphor (Genocide, Civil War, Geographic Location) on graphic rating, approaching significance $F(2, 99; MSe = 1.996) = 2.82, p = .06$. Specifically, the graphic depicting the metaphor of genocide was rated as more like the definition of genocide when presented alongside two other graphics ($M = 3.71, SD = 1.38$) then when presented alongside two other definitions ($M = 2.92, SD = 1.53$).

Theoretical and Educational Significance

These results support a diverse set of findings of relative choice behavior as they apply to visualizations. When participants are presented with one definition and asked to rate multiple graphics on the definition-graphic correspondence, the graphic which matches the definition is rated as more similar compared to the same graphic when judged against multiple definitions. The findings are discussed in the context of frames and the theory of rationale choice relative to learners' interpretation of the graphics they view when accompanying text. The findings are important for research on visualizations because it suggests that the interpretation of graphics is not contextually

independent and distinct. Instead, the interpretive judgments learners make of graphics are relative to the frame of reference in which they are embedded.

PAPER PRESENTATION

Learning from pictures: the role of physical similarity

Lisanne van Weelden, Tilburg University, Netherlands; Alfons Maes, Faculty of Humanities Tilburg University, Netherlands; Joost Schilperoord, Tilburg University, Netherlands

Visual metaphor is a well-known template in genres like cartoons, advertisements and study books. Several studies on visual metaphors suggest that physical similarity between object representations facilitates finding meaningful relations between them. The present study investigates how viewers draw attributive and relational information from representations of objects and how physical similarity helps finding relations between metaphorically related concepts. Our starting point is the idea that similarity in shape leads to the interpretation of both objects being of the same type, which subsequently facilitates creating a joint conceptual category.

In our experiment, forty-two 11 year-olds compared two pictures (a source and a target, e.g. a leopard and a motorcycle), which were either physically similar or physically dissimilar. When the source picture was presented (e.g., a leopard), the participants had to call out as many features as came to mind. When the target picture was presented (e.g., a motorcycle), participants had to mention as many correspondences between source and target as they could. The analyses focused on the number and types (attributive or relational) of correspondences, the number of repetitions of predicates, and the number of explicit comparative expressions.

Preliminary results show that physical similarity between objects results in more comparative expressions based on relational predicates. For example, when 'fast' was already mentioned for the leopard, we found more comparisons like 'the motorcycle and the leopard both go very fast' when the motorcycle and the leopard were physically similar than when they were not.

One of the reasons why pictures are often used in learning situations is that they enable learners to draw propositional information from them. Drawing information from multiple objects within one visual array, however, is far from straightforward, as pictures lack real syntax. Physical similarity and alignment between object representations can be used to suggest meaningful relations between depicted objects.

The present paper investigates the role of physical similarity between objects in finding meaningful relations between metaphorically related concepts. We presented forty-two 11 year-old children with pairs of metaphorical pictures, which were either physically similar or not, and asked them to produce as much correspondences as they could. Metaphor is a matter of finding meaningful relations between two concepts, in an attempt to understand one concept (the target) in terms of another (the source) (Bowdle & Gentner, 2005; Lakoff & Johnson, 1980). By using metaphoric picture pairs, for example, a motorcycle (target) paired with a leopard (source), we created a natural elicitation task situation, which enabled us to investigate the basic processes in metaphoric conceptualization: comparison and categorization. According to Lakoff and Johnson (1980), metaphor is not so much a matter of language, but a matter of mental conceptualization, which implies that other representational modes (like pictures) are equally well able to elicit metaphoric processing. This is confirmed by the use of metaphoric visuals in many genres like advertisements, cartoons and learning materials. However, little is known about how viewers and learners construct metaphoric conceptualizations on the basis of visual input. In studying metaphor processing based on language, two types of correspondences between source and target are distinguished: low level attributive relationships (e.g., the leopard and the motorcycle having a similar slender shape) and higher level conceptual-relational relationships (e.g., the ability of leopards and motorcycles to run/ride very fast). We expect that the mere physical similarity of objects in metaphoric pictures affects finding these relationships. By using physically similar vs. dissimilar pairs (see figure 1), we exploit this typical characteristic of the visual medium. Hence, the main questions we address in the present study are how viewers draw attributive and relational information from representations of objects and how perceiving physical similarity between objects stimulates viewers to find metaphorical relationships between them. Based on the idea that 'the nature of an entity is its shape', we hypothesize that similarity in shape leads to the interpretation of both objects being of the same type, which subsequently facilitates creating a joint conceptual category. Hence, we predict that it is easier to find a metaphorical relationship between two objects when they are physically similar than when they are not. So, we expect physical similarity between objects to stimulate not only low level attributive

correspondences, but also higher level conceptual relations (Phillips & McQuarrie, 2004; Schilperoord, Maes, & Ferdinandusse, 2009; Teng & Sun, 2002)

.For our experiment we created 14 picture pairs, each consisting of a source, e.g. the leopard (either physically similar or dissimilar), and a target object, e.g. the motorcycle. The source objects were always natural objects (like a leopard, a giraffe, the sun, a hand), whereas the target objects were artifacts (like a motorcycle, a lighthouse, a clock, a computer mouse). The source and target picture were successively shown. When the source picture was presented, the participants had to call out as many things as came to mind within a 15 second time span. When the target picture was presented, they had to mention as many correspondences between target and source as they could within a 20 second time span. To control for any interference effects between the picture pairs, participants played a word-finding-game in between each picture pair.

The analyses focused on the number and type (attributive or relative) of predicates mentioned for the source and target, on the number of repetitions of predicates as compared to the source, and the number of explicit comparative expressions in the mentioned correspondences. Preliminary results show that physical similarity between picture pairs leads to more comparative expressions based on repetitions of relational predicates. For instance, when 'dangerous' was already mentioned for the leopard, we found more comparisons like 'the motorcycle and the leopard are both dangerous', when the motorcycle and the leopard were physically similar than when they were not.

PAPER PRESENTATION

An intervention study on Mind Mapping skills and text processing in fifth and sixth grade

Emmelien Merchie, Ghent University, Belgium; Hilde Van Keer, Ghent University, Belgium

Due to the exponential increase of knowledge in our information society, the need arises to support students in dealing with this information and engaging in self-regulated learning (SRL). This especially becomes essential from the age of 11-13, when children spend increasingly more time on learning from texts. The present study is embedded within the cognitive component of SRL, focusing on learning strategies and tactics students can apply for effectively processing, acquiring, and learning information. Working with graphic organizers, such as Mind Maps, seems promising in supporting students in this domain. This study addresses two main research questions by means of a repeated measures design in authentic fifth and sixth-grade classes (N = 62 students). We first focused on whether a positive evolution in Mind Mappings skills can be realised through a ten weeks during Mind Mapping intervention. Secondly, we investigated whether children make a significant progress in processing textual information by Mind Mapping throughout the intervention. The results of the repeated measures analyses reveal a significant evolution in Mind Mapping skills, indicating that Mind Mapping can be learned by fifth and sixth graders in a relatively short period of time. Children improve significantly in applying different Mind Map rules and in processing textual information in a Mind Map in a structured way.

Theoretical background

The exponential knowledge increase in our information society requires skills and strategies for realising efficient and effective processing and acquisition of information (Crick, 2007). In this respect, self-regulated learning (SRL) plays a growing role in educational research. SRL can be defined as a planned and cyclical way of regulating thoughts, feelings, and actions to meet personal goals (Boekaerts, Pintrich, & Zeidner, 2000) and includes a motivational, metacognitive and cognitive component (Zimmerman, 1990). The present research focuses on the cognitive component, referring to learning strategies and tactics students apply (Pintrich, 2004). The focus lies on cognitive processes and strategies for effectively processing and acquiring new information and linking it to prior knowledge (Cornford, 2002). In this domain, researchers call for approaches supporting children in processing, acquiring, and learning texts in a structured way (Novak, 2002). These skills play an important role, especially from the age of 11-13 when children spend more time on learning from texts (Rawson & Dynlosky, 2007). The use of graphic organizers, more specifically Mind Maps

(MM) (Buzan, 1974), seems promising in helping children in this respect (Vekiri, 2002). MM are typified by specific characteristics (e.g. dimensionality, colours, and images) determining the effectiveness of how well the text information is structured and learned (Buzan & Buzan, 1995). Several theoretical models underpin the use of graphic organizers, e.g. the Dual Coding Theory (Paivio, 1991) and Cognitive Load theory (Sweller & Chandler, 1994).

Research questions

We first focus on whether there is an evolution in Mind Mapping skills. Since it is important to respect the specific characteristics of MM determining their effectiveness, we investigate whether children significantly improve in applying the MM rules (Buzan & Buzan, 1995). Furthermore, we investigate whether children make a significant progress in processing textual information by using Mind Mapping.

Research method

Design. The study consisted of a ten weeks during intervention (one session of 50 minutes per week) in authentic classes and addresses the research questions by means of a repeated measures design (pretest, intermediate test, and posttest). In the intervention, children gradually learned how to Mind Map from a trained researcher.

Participants. A total of 62 primary school children of fifth and sixth grade participated in the study (4 classes from 2 different schools).

Instruments. The repeated tests consisted of independently making a MM of an informative text within 30 minutes. For each measurement occasion a different, but equivalent text was used. Afterwards, the characteristics and the quality of the collected 186 MM were scored. Therefore, an analytic scoring rubric containing two broad categories ('shape and organisation' and 'content') was used. Within these categories, subcomponents were identified based on the Mind Map rules (e.g. using a radial structure) and relevant content elements (e.g. relevance of key words) (Taricani & Clariana, 2006).

Data Analysis. The scores on the rubric were analysed quantitatively with One-Way Repeated-Measures Analyses of Variance.

Results

As to the first research question, a significant evolution was found on the use of capitals on the main branches and little letters on the other branches ($F(2,58)=8.754$, $pF(2,58)=5.609$, $p=0.006$). Further, the readability of the MM is significantly better ($F(2,58)=6.314$, $p=0.003$), keywords are better positioned ($F(2,58)=3.281$, $p=0.045$), and children make significantly more clusters at the end of the intervention ($F(2,58)=9.469$, $pF(2,58)=11.238$, p

As to the second research question regarding the processing of textual information in the MM, the children use significantly more information ($F(2,58)=82.990$, $pF(2,58)=14.397$, $p=0.000$). Words in a branch are better matched and associated ($F(2,58)=10.390$, $pF(2,58)=14.397$, $pF(2,58)=15.451$, $p=0.000$) and the children get overall better scores on their MM ($F(2,58)=125.468$, p Figure 1 illustrates the evolution of one participant's MM (pretest, intermediate, and posttest).

Significance of the research

The present study is significant for both educational research and practice. As regards the relevance for research, the study works on the existing gap in the current literature on effective approaches for supporting primary school children to structurally process and learn textual information. In this respect, the study enters upon an undeveloped research domain for this age group and might inspire other educational researchers to investigate the use of MM in primary school grades more thoroughly. As to educational practice, the present study demonstrates that elementary school children are able to learn to process informative texts by means of MM. Further, the results imply that by using MM in daily educational practice, teachers can stimulate and evaluate SRL-activities of children.

PAPER PRESENTATION

Learning from Text with Instructional Pictures: Tracing Cognitive Processing Through Eye Movements

Nicola Ariasi, University of Padova, Italy, Italy; Lucia Mason, University of Padova, Italy; Patrik Pluchino, University of Padova, Italy; Caterina Tornatora, University of Padova, Italy

This study first investigated whether an illustrated text would be more effective than a non-illustrated text in promoting a better learning performance. Secondly, it examined whether reading a text with a schematic picture or a text with a detailed picture would induce different cognitive processing, as revealed by eye movements, and learning outcomes.

As concerns the cognitive processing during reading, two fine-grained indices of eye movements were computed and used in the analyses: look-from fixation time to trace the integration of verbal and pictorial information, and look-back fixation time to examine the extent to which a particular area of interest was reinspected. Individual differences, such as prior-knowledge, reading comprehension, verbal and visuo-spatial working memory, and spatial ability, were also considered.

Sixty-five eighth graders were involved in a pretest, immediate posttest, and delayed posttest design. They were randomly assigned to a different reading condition. Findings revealed that, overall, an illustrated text was more effective in enhancing readers' learning performance compared to a non-illustrated text. Furthermore, readers of the text with the detailed picture outperformed readers of the text with the schematic picture at the immediate but not delayed posttest. Eye-movement analyses revealed that readers of the text with a schematic picture went further a simple rereading of some parts of the materials, attempting more to integrate verbal and pictorial information. The differential roles played by a schematic vs. a detailed picture in the cognitive processing of an illustrated scientific text are discussed.

Theoretical Framework and Aims

Research investigating learning from verbal and visual material is particularly important since textbooks, especially in domains like science, contain various kinds of instructional pictures. They are supposed to enhance learning (Mayer, 1989; Mayer & Gallini, 1990) but research has indicated that it is not always true that "a picture is worth a thousand words" (Mayer & Sims, 1994). Research has also posited that successful learning from illustrated text requires the information provided by the pictures to be integrated with information provided by the text, which can make high cognitive demands on learners (Ainsworth, 2006; Bartholome & Bromme, 2009; Florax & Ploetzner, 2010; Schnotz & Bannert, 2003). In agreement with Mayer (2001), Schnotz (2002) has used separate processing systems for verbal and pictorial information. However, he focused on the essential differences between the two sign systems and conceived the process of integration of verbal and pictorial information as a structure-mapping process (Gentner, 1989). The corresponding elements of the two different representations, and their relationship, are mentally mapped (Schnotz, 2002).

Based on these research issues, this study compared two kinds of potentially useful pictures, detailed vs. schematic, which illustrate the same text in order to examine the integration process of verbal and pictorial information. A detailed picture is an illustration that depicts the theme of a text in a rich representational, but not decorative, way since its function is to convey information. Therefore, it does not include seductive details (Harp & Mayer, 1998). A schematic picture is a simplified illustration of the text content, which does not resemble the thing it represents, but is also not so abstract as to require interpretation. The process of information integration was traced through fine-grained eye-movement analysis (Hyona, 2010; Hyona, Lorch, & Rinck, 2003; Inhoff & Radach, 1998). Most research on learning from text and pictures has investigated outcomes. Fewer studies, however, have focused on the cognitive processes, and almost all have used thinking-aloud methodology (e.g. Butcher, 2006; Cromley, Synder-Hoga, & Luciw-Dubas, 2010). Even the few recent multimedia studies that have measured eye fixations have not used fine-grained

indices of visual attention allocation to trace the process of integration between text and illustration (Jarodzka, Scheiter, Gerjets, & van Gog, 2010; Sanchez & Wiley, 2006; Schwonke, Berthold, & Renkl, 2009).

To extend current research, the following research questions guided the study: (1) Is a text with a picture, either schematic or detailed, more effective for learning than the same non-illustrated text? In particular, is a schematic picture more effective than a detailed picture? (2) Does reading a text accompanied by a schematic picture induce cognitive processing which is different from reading a text with a detailed picture, as revealed by eye-movement measures? For research question 1, we first hypothesized that an illustrated text would be more effective than a non-illustrated text. We also expected that the schematic picture would be superior since it would facilitate the mapping process of the corresponding elements of the two kinds of representation. In other words, this correspondence would become more salient. For research question 2, we expected that the two pictures would induce different processing. The schematic illustration should require shorter reinspection time than the detailed, but should stimulate more the integration of text and picture through structure mapping.

Method

Sixty-five eighth graders (mean age=13.8; girls=33) were involved in a pretest, immediate posttest and delayed posttest design. They were randomly assigned to one of three reading conditions: text only, text with a schematic picture, or text with a detailed picture illustrating the structure of volcanoes. The text and pictures were presented in the same position on a computer screen, taking into account the spatial contiguity principle. The pictures were of the same size. Participants' prior knowledge, verbal working memory, visuo-spatial working memory, spatial ability, and reading comprehension were measured. The integration of text and picture was measured by means of a specific fine-grained measure of eye movements, look-from time, that is, the time a learner spends refixating the text information while inspecting the picture. We also computed look-back time, that is, the time a reader spends refixating the text information or picture after the first pass, which reflects delayed, strategic processing (Hyona, Lorch, & Kaakinen, 2002).

Results

Preliminary analyses revealed the equivalence of the three groups for all the examined measures.

Off-line Products

Findings showed a significant time x reading condition interaction, $F(4,120)=3.597$, $p=.008$, $\eta^2p=.11$. At immediate posttest, readers in the text only condition ($M=10.96, SE=1.30$) learned less than readers of the schematic picture text ($M=13.77, SE=1.40$) and readers of the detailed picture text ($M=16.85, SE=1.28$). Regarding the delayed posttest, the learning performance of readers of the schematic picture text ($M=11.73, SE=1.24$) was slightly better than readers of the detailed picture text ($M=11.24, SE=1.16$).

On-line Processes

Regarding the integration between pictorial and text information, only readers in the two illustrated conditions could be compared. Findings revealed a significant reading condition x reading time interaction on look-back, $F(2,37)=7.130$, $p=.002$, $\eta^2p=.28$, and look-from fixation times, $F(2,37)=4.662$, $p=.016$, $\eta^2p=.20$. Readers of the text illustrated with the detailed picture ($M=10.52, SE=3.04$, in sec) backtracked the picture for longer (looks-back) than students who were given the schematic picture text ($M=5.50, SE=3.26$, in sec). On the other hand, the latter ($M=8.00, SE=1.77$, in sec) made longer returning fixations from the picture to the text information (looks-from) compared with students who inspected the detailed picture ($M=7.87, SE=1.65$, in sec).

Scientific and educational significance

This study has scientific significance in that it seeks to extend current research by providing evidence of the differential roles played by a schematic vs. a detailed picture in the cognitive processing of an illustrated scientific text. The study is also of educational significance as it indicates the different benefits associated with the two kinds of instructional pictures that are often provided in science textbooks. More detailed or schematic illustrations could be used in keeping with the purpose of presenting visual aids to support the construction of scientific knowledge through the appropriate cognitive processing of information.

PAPER PRESENTATION

Seductive details in multimedia messages

Gunter Daniel Rey, Institute of Psychology, Germany

The seductive detail principle asserts that people learn more deeply from a multimedia presentation when interesting but irrelevant adjuncts are excluded rather than included. However, the results of previous studies about this principle are inconsistent and these studies contain methodological problems. The recent experiment attempts to overcome these problems. Students ($N = 108$) used an introductory text to learn fundamental concepts about the development of stars and then took a retention and transfer test as dependent measures. Each learner was randomly assigned to one cell of a 2 (with or without seductive text passages) \times 2 (with or without seductive illustrations) between subjects factorial design. Students who did not receive seductive text passages spent less time with the multimedia presentation and performed better on retention, but not on transfer than did learners receiving seductive text passages. Seductive illustrations did not significantly influence learning performance or time spent with the instructional material.

Introduction

Seductive details are interesting but irrelevant details, which are not necessary to achieve the instructional objective (Mayer, 2005). On one hand, many teachers, text book writers and multimedia designers add these details in an instructional message hoping to energize a learner to pay more attention to the material and to foster learning outcome (cf. Harp & Mayer, 1997). On the other hand, the seductive detail effect assumes that removing seductive details improves learning outcome, for example, by shifting learners' attention from irrelevant to relevant details.

A review concerning seductive details reveals that several results exist that either support or contradict the seductive detail effect. First, for seductive text passages, two out of 11 experiments clearly support the seductive detail effect. Four out of 11 studies contain mixed results concerning the effect, while five experiments clearly did not support the effect. Second, for seductive illustrations, four out of 12 studies included results clearly supporting the negative impact of seductive details. Six out of 12 experiments contain mixed findings, while another two studies clearly contradict the seductive detail effect.

Critics could argue that the inconsistent findings in previous studies about the seductive detail effect could be to some extent attributed to three methodical problems. First, studies indicating a significant effect for seductive illustrations included different confounding factors. For example, studies did not compare a seductive illustration group with a control group, but combined seductive illustrations with seductive captions for these illustrations. Second, students' prior knowledge of the instructional material and time spent with the instructional material were only rarely used in the statistical analysis (e.g., considering these variables as covariates). Third, most studies investigating the seductive detail effect forego to conduct and report power analyses. Without power information the null hypothesis cannot be accepted on the basis of a nonsignificant finding. The present study tried to overcome these three methodological problems.

Method

Participants

The participants were 108 undergraduate students recruited from the University of Trier (Germany). The mean age of the participants was 22.3 ($SD = 4.3$) years and the percentage of women was 70.4%. Results of a pretest indicated that students had low experience in the presented instructional material.

Materials and Design

For each participant, the computer materials contained an instructional page, the pretest, an introductory text about the development of stars, as well as a retention and a transfer test. The pretest included four multiple choice questions (five response options per question where one to four answers per question could be correct) about the life cycle of a star. The multimedia presentation contained 20 slides, where 4 slides included the heading and three subheadings of the text (i.e., origin of a star, course of life of stars and death of a star). The 16 text slides contained exact 700 words in the condition without seductive text passages.

The retention test consisted of 15 multiple choice questions. Each of the questions included five response options where one to four answers per question were correct. All retention questions could be answered with the information that was given in the text material without the inference of additional information. The transfer test consisted of five multiple choice questions (five response options per question where one to two answers per question were correct). In all transfer questions inferences had to be drawn from the presented information in the visualization.

Each student was randomly assigned to one cell of a 2 \times 2 between subjects factorial design (27 participants for each cell). The seductive text passages (i.e., the first between-subject factor) consisted of about two additional sentences per slide (overall 448 additional words). The seductive illustrations (i.e., the second between-subject factor) consisted of 19 pictures, where only one picture per slide was presented. Seductive text passages as well as seductive illustrations were chosen with regard to interestingness on the basis of six raters in the fore field of the study.

Procedure

The participants processed the instructional material at their own pace and without any time limit. On average, they spent about 10-15 minutes with the instructional material. First, they worked on the pretest followed by the (illustrated) text material. Immediately after the instructional material, they answered the same retention and transfer questions within an abundant time limit of 15 minutes (all participants finished before time was called).

Results & Discussion

Learners who did not receive seductive text passages spent less time with the instructional material and performed better on retention, but not on transfer than did learners who received seductive text passages. Seductive illustrations did not significantly influence retention and transfer performance or time spent with the multimedia presentation. Using prior knowledge scores as well as the time spent with the multimedia presentation as covariates assures that learning differences cannot be attributed to differences in prior knowledge or solely to time differences in the different groups. The sufficient power of the experiment warrants that null hypotheses can be accepted for all nonsignificant findings (for an effect size of $f^2 = .15$).

Learners receiving seductive illustrations could presumably rapidly recognize that a seductive illustration contains no relevant information and therefore skip these illustrations. On the contrary, seductive text passages probably contain a higher amount of information content than seductive illustrations. In addition, seductive text passages were embedded in the relevant text with the same layout and typeface. Therefore, learners cannot neglect the seductive text passages and spent considerably more time with the instructional material when these text passages were included.

Possibly, the difference between retention and transfer performance with regard to the experimental conditions could be explained with differences in the sensitivity of the two measures (e.g., using only five items for the transfer test in contrast to 15 items for the retention test). On the practical side, the recent findings show that seductive text passages can not only increase time needed to process a multimedia instructional message, but also can impair learners' retention performance. On the theoretical side, the present results partly confirm the coherence principle (Mayer, 2005) of the cognitive theory of multimedia learning.

PAPER PRESENTATION

A picture among pictures: A classification system for instructional visualizations

Halszka Maria Jarodzka, Open University of the Netherlands, Netherlands; Birgit Karoline Imhof, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany

The use of instructional visualizations has become very popular in the last decades, especially due to the rapid development of technical solutions. Visualizations do not only vary with regard to their structural features (e.g., dynamism, interactivity), but they also have different functional features (e.g., decoration, representation, organization). Research has investigated these two dimensions particularly in learning contexts. In addition, a third dimension of visualizations, namely the depicted contents, has been identified. However, the high variability of visualizations is challenging with regard to generalizability of empirical research results found with a specific type of instructional visualization. Therefore, a generic classification system is needed to be able to structure the wide body of research. Although, some attempts to address the classification of visualizations have already been made, those focus only on either structural or functional dimensions of visualizations. The current work reviews educational literature on all three aforementioned dimensions aiming at developing a classification system covering the structural features, the functions, and the depicted contents and thereby allowing to assign visualizations to classes of similar visualizations regarding these aspects. The classification system (in form of a questionnaire) was evaluated with ten subjects classifying six different visualizations in order to test the interrater reliability, to assess the usability during filling in the questionnaire, and to investigate its applicability to different types of visualizations. Data analyses revealed high, or

close to high interrater reliabilities for all six visualizations. These results indicate that a questionnaire-based classification system can be used to objectively classify visualizations.

The use of visualizations for depicting real life objects and relationships of objects has a long history. Given the technological development in the last decades, we are confronted with more and more visualizations in our everyday live ranging from simple black-and-white line drawings or paintings to highly realistic animations, photographs, films, or 3D-visualizations, to only name a few. Especially, in the context of education visualizations like diagrams, illustrated textbooks, educational films, and multimedia products play nowadays a stronger role. Despite the large use of visualizations in instructional contexts, it is still not clear, whether and when we benefit from visualizations or whether and when they are rather harming for learning. Therefore, it is crucial to identify the conditions under which specific instructional visualizations are beneficial.

Deciding about the usefulness of visualizations in a certain learning context requires to consider and to investigate various aspects of visualizations in a systematic way. Therefore, a classification system for visualizations is needed to identify possible moderators for the effectiveness of visualizations. Such a classification system can be used to categorize visualizations into classes of similar and dissimilar visualizations in order to transfer important decisions about, for example, the usefulness of visualizations in given contexts from one visualization of the class to another.

Research has already identified several important aspects of visualizations, as the structural features or the functions of visualizations (e.g., Lohse, Biolsi, Walker, & Rueter, 1994). Unfortunately, in existing taxonomies only one of these aspects is regarded, whereas other dimensions of visualizations are disregarded or even ignored although it is important to consider all aspects of a single visualization in order to make statements about its usefulness. We assume that a successful classification system has to be extended by adding a third dimension, namely the content depicted in the visualization. Many instructional obstacles, approaches, or goals are closely tied to content domains. Therefore, we propose a classification system for visualizations that comprises not only structural and functional features of visualizations, but also its contents and that is based on recent literature (Imhof, Jarodzka, & Gerjets, 2009). In order to provide a practicable and reliable classification system we chose a questionnaire format which allows researchers, developers, and users to characterize different aspects of visualizations that might contribute to their instructional effectiveness. The development of a classification system for visualizations is a first step in clarifying the question under what circumstances what kinds of visualizations are effective. We choose a broad approach, including relevant features of visualizations identified in current multimedia research as well as in other research fields, as for instance film and text comprehension, or research on television. As structural features we define the dimension of visualizations that focuses on the form and the physical aspects (e.g., color, dynamism) of the visualizations and is objectively observable. As functional features we define the intended uses and purposes of visualizations (e.g., motivating, guiding attention, representing). And besides these structural and functional features, visualizations have a certain content that can be described with regard to its genre, target audience and other aspects.

The usability of the proposed questionnaire was tested with ten independent raters, who rated six different visualizations. The visualizations comprised a computer animation about cancer, an impressionistic painting, a static text-picture combination, an animated cartoon, a section from a silent film, and a section from a television movie. To test the interrater reliability for all possible 45 pairwise comparisons between the ten raters Craméers V (ranging from 0-1) was calculated for each of the six visualizations. Four of the six tested visualizations (computer animation, painting, silent film, and movie), reached high interrater reliabilities for the ten independent raters ($V > .60$). The remaining two visualizations (static text-picture combination and animated cartoon), reached a close to high interrater reliability (both V s = .57).

A first evaluation of the developed classification system revealed a high or almost high interrater reliability for six different test visualizations. Interestingly, the two visualizations that achieved only a medium interrater reliability entailed a rather low amount of realistic detail compared to the four visualizations with high interrater reliability. This result indicates that schematic visualizations might be seen more diverse than realistic ones. This effect can go to the fact that realistic visualizations are more similar to our everyday experience that provides a common ground for the interaction with our peers. In contrast, schematic visualizations are only encountered in specific situations (e.g., learning contexts) and thus, their familiarity and, consequently, their assignment to classes might differ more among different expertise levels. Moreover, the two visualizations with medium interrater reliability differed from the other visualizations also with regard to the following features: the static text-picture combination was the only test visualization that (a) was combined with written text, that (b) consisted of multiple static pictures, and that (c) conveyed procedural instructions. The animated cartoon was different from the other visualizations in that it was (a) longer than the other ones and entailed (b) more different sections than the other dynamic visualizations. A longer,

respectively information-rich visualization might promote more possibilities for misinterpretations. This might lead to different classifications.

To identify specific difficulties in classifying certain types of visualizations further research is needed. In particular, the interrater reliabilities for the three dimensions of the classification system and the individual items should be investigated separately to identify problematic items. Eventually, the classification system may be a helpful step towards identifying individual learner competences and beneficial circumstances that are important for the effectiveness of different types of visualizations. It might also help to shed some light on inconsistent results concerning the effectiveness of instructional visualizations. In particular, a meta-analysis using this type of classification to review previous research on visualization effects might substantially contribute to future research on instructional visualizations.

PAPER PRESENTATION

The Role of Textual Information on Dynamics in Learning with Dynamic or Static Visualizations

Tim Kuhl, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany; Katharina Scheiter, Knowledge Media Research Center, Germany

An advantage of dynamic visualizations for learning is that they can directly depict dynamic features like changes in velocity. In contrast, when using static visualizations, learners need to infer these dynamic features by themselves, at least if these are not conveyed by an additional external source such as text. To address these issues, the effectiveness of learning with either text-only, text with dynamic visualizations, or text with static visualizations was investigated in 2 experiments, which differed with regard to the information presented in the text. While in Experiment 1, all dynamic information was explicitly described in the text, in Experiment 2 this information was not described, but had to be inferred. In both Experiments, learners were assigned to one of the three conditions specified above, and learning outcomes were measured by means of factual knowledge tests, transfer tasks as well as static and dynamic pictorial tasks. In Experiment 1, results revealed that learners in the two visualization conditions outperformed learners in the text-only condition solely for pictorial tasks. No differences were observable for any learning outcome measure between the two visualization conditions. In Experiment 2, results revealed that learners in the two visualization conditions outperformed learners in the mere text condition for transfer tasks and for pictorial tasks. Moreover, the dynamic visualization condition was superior to the static visualization condition for transfer tasks and for dynamic pictorial tasks. These findings of both experiments point to the importance of textual information on dynamic features when comparing dynamic and static visualizations.

Introduction

There is strong empirical evidence that people learn better with text and visualizations than with text alone (Mayer, 2001). This effect seems to be more pronounced for transfer than (verbal) factual knowledge tasks (Mayer, 2001). Moreover, with respect to factual knowledge tasks, the instructional advantage of text and visualizations has been shown to be especially accentuated for pictorial tasks, but less accentuated and sometimes even non-existent for verbal tasks (cf. Baker & Dwyer, 2000).

Instructional Advantages of Dynamic and Static Visualizations

When comparing the effects of static to dynamic visualizations (e.g., animations), it is suggested to take a closer look at the conditions under which dynamic visualizations might be best suited for instructional purposes (cf. Schnotz & Lowe, 2008). A crucial difference in the processing of dynamic compared to static visualizations might refer to the fact that dynamic visualizations directly depict dynamic features like changes in velocity, so that this dynamic information can be simply read-off. In contrast, when learning with static visualizations these dynamic features have to be inferred by the learner (Experiment 2) if they are not conveyed by an additional external source such as text (Experiment 1). However, integrating textual information on dynamic features with static visualizations - or even inferring this information - may be considered as a resource-intensive process (cf. Schnotz & Lowe, 2008). Therefore, dynamic visualizations should be best suited to convey a content in which the understanding of dynamic interrelations is crucial (congruence principle, Tversky, Bauer-Morrison, & Béêttrancourt, 2002).

Hypotheses

To summarize, we expected learners in the two visualization conditions to outperform learners in the text-only condition. This superiority should be more pronounced for pictorial and transfer tasks as opposed to verbal factual knowledge tasks. Moreover, we expected learning with dynamic visualizations to be superior to learning with static visualizations, particularly with respect to transfer, as well as dynamic pictorial tasks (see below for a description). This superiority should be even more accentuated, if dynamic features have to be inferred and are not given by text when learning with static visualizations.

Method for Experiments 1 and 2

Forty-six University-students in Experiment 1, and 55 University-students in Experiment 2, respectively, were randomly assigned to one of three conditions: a text-only, a text with dynamic visualizations, and a text with static visualizations condition. In both Experiments, learning outcomes were measured by means of verbal factual knowledge, transfer, and pictorial tasks. The pictorial tasks were further divided in static and dynamic pictorial tasks. For the dynamic pictorial task, the correct movement of a planet around the sun had to be recognized.

The chosen domain (Kepler's second law) dealt with changes in the velocity of the planetary motion around the sun. For this instructional material, the direct depiction of these dynamic features is basically the sole important dimension in which static and dynamic visualizations differ.

The main difference between Experiment 1 and 2 was the information conveyed by the text: In Experiment 1, the dynamic features were explicitly described in the text, whereas in Experiment 2, we used a reduced text version, in which the dynamic features were not explicitly described, but had to be inferred (see Figure 1).

Results

Experiment 1

Planned contrasts between the two visualization conditions and the text-only condition revealed no differences for verbal factual knowledge ($p = .20$) or transfer tasks ($p = .33$), but for the static ($p = .10$). However, learners in the dynamic visualization condition identified the correct movement in the dynamic pictorial task faster than learners in the static visualization condition ($p = .04$).

Experiment 2

Planned contrasts between the two visualization conditions and the text-only condition revealed no differences for verbal factual knowledge tasks ($p = .40$), but for transfer ($p = .01$), for static (p

Summary & Discussion

When using an enriched text in which the dynamic information was explicitly described (Exp. 1), we observed learners in the two visualization conditions to outperform learners in the text-only condition solely for pictorial tasks. The latter might be interpreted as learners receiving text only might have difficulties in building an adequate pictorial mental model of the topic. However, since text was sufficient to solve the transfer tasks (and the addition of visualizations was obviously not necessary), the finding of the instructional equality of dynamic and static visualizations for transfer tasks is consistent.

However, when the dynamic information in the text was reduced and this information had to be inferred, our hypotheses were mainly confirmed: Learners in the two visualization conditions performed better than learners in the text-only condition, and learners receiving dynamic visualizations outperformed learners receiving static visualizations for transfer and dynamic pictorial tasks.

Taken together, these results suggest that the information described in the text might moderate the instructional effectiveness of dynamic and static visualizations and thus determines under which conditions dynamic visualizations might be particularly helpful.

PAPER PRESENTATION

Does external rotation facilitate recognition of a spatial structure?

Stefan Munzer, Saarland University, Germany

Animations may facilitate understanding of spatial structures. The present study investigated whether an external rotation as opposed to internal (mental) rotation of a spatial structure enhanced recognition memory for rotated test exemplars. In addition, the study examined whether external rotation compensated for low mental rotation ability. Participants were shown simple 3-D building structures. In the external rotation condition, animation was presented with the building structure rotating from 0° to 180° . In the internal rotation condition, a static picture was shown. Subsequently, participants had to decide from memory whether a test picture of a rotated (50° , 90° , 170°) building structure represented a structure identical to the studied one. A large facilitating effect of external rotation was found for reaction times. No effects were found for accuracy. Based on reaction times and accuracy in a chronometric mental rotation test, participants were divided in high vs. low mental rotation ability groups. Both groups benefitted from external rotation. With animation, low ability individuals reacted as fast as high ability individuals who had studied static pictures. It is concluded that external rotation can facilitate the understanding of a spatial structure, compensating for low spatial ability.

Aim of the study

Animations may facilitate learning by supplanting internal (mental) visual-spatial processes (Salomon, 1994). Animations can externalize processes that change views on a spatial structure, substituting potentially difficult internal processes (e.g., mental rotation). On the other hand, animations are transitory and may be distracting. Visual-spatial mental abilities play an important role for learning from external visualizations. This is apparently true for learning with animations (e.g., Cohen & Hegarty, 2007), implying that higher abilities are required for using animations efficiently. However, if animations actually support visual-spatial processing, then animations should be able compensate for low visual-spatial ability.

The present study examines whether the external rotation of a spatial structure facilitates the recognition of the spatial structure from memory. It is hypothesized that the external rotation of a spatial structure will enhance recognition (H 1). It is furthermore hypothesized that external rotation can compensate for low mental rotation ability (H 2).

Method

Participants. Thirty-six participants (students, 18 women) took part in the study (age $M = 23.31$, $SD = 3.66$).

Materials. A chronometric mental rotation test was constructed similar to a test developed by Jansen-Osmann and Heil (2007), using PMA symbols (Thurstone, 1958). Participants decided whether a rotated (0° , 45° , 90° , 180°) symbol shown on the right was the same as the symbol shown on the left (Fig. 1). The test comprised 60 items presented in random order.

--- Figure 1 ---

The experimental study and test materials comprised simple 3-D building structures (Fig. 1). In the external rotation condition, participants studied a video that showed a clock-wise rotation from 0° to 180° . In the internal rotation condition, participants studied a static picture. The screen was cleared. Then a static test picture was presented showing a building structure (rotated to 50° , 90° , or 170°) which represented either the same structure or a mirrored version of it (Fig. 1). Participants decided on the identity of the spatial structures from memory. Fifty-four items were presented. Half of the test pictures were same. Each viewing angle (50° , 90° , 170°) was shown equally often.

The chronometric mental rotation test was administered first. Internal vs. external rotation conditions of the experiment were blocked and presented to all participants. Half of the participants first received the internal rotation block, the other half first received the external rotation block.

Results

A one-factorial analysis of variance with repeated measurement on the rotation angle factor (45° , 90° , 180°) was performed for the chronometric mental rotation test data. No effects were found for accuracy. A significant effect was obtained for reaction times which increased almost linear with rotation angle, $F(2,68) = 15.354$, p

Preliminary analyses of the experimental data revealed that participants were accurate and fast with external rotation when tested with the 170° test picture. Participants presumably accessed visual sensory memory of the 180° rotated view (the final state of the external rotation) to make the decision for the 170° test picture. Effects based on this phenomenon were considered trivial. Therefore, the data were analyzed without the 170° viewing angle.

--- Figure 2 ---

Considering group differences in mental rotation ability in addition to rotation conditions and viewing angle resulted in a 2 (50° vs. 90° viewing angle) $\times 2$ (internal vs. external rotation) $\times 2$ (high vs. low mental rotation ability) mixed three-factorial design. No significant main effects and no interactions were found for accuracy (ability, $F(1,34) = 2.522$, ns; all other F 's ns). For reaction times, a large main effect of rotation condition was found, $F(1,35) = 23.223$, $p < .001$, F ns,

and no interaction between viewing angle and rotation condition was revealed, F ns. In addition, a marginally significant main effect of ability was found, $F(1,34) = 4.143$, $p = .05$, partial eta square = .11. No interaction was found between ability and rotation condition, F ns.

It is concluded that external rotation facilitated processing of the spatial structure as indicated by faster reaction times, supporting hypothesis H 1. Furthermore, with external rotation, low mental rotation individuals performed at the level of high mental rotation individuals after studying static pictures (see Fig. 2), supporting hypothesis H 2. High mental rotation ability individuals also benefitted from external rotation. The effects of ability and external rotation were additive.

Theoretical and educational significance

In many domains (biology, geography, mechanical systems, etc.), the understanding of the spatial configuration of components of a system is a precondition for understanding causal processes. Results of the present study show that the understanding of spatial structures can be facilitated through well-directed animations in multimedia learning. In addition, individuals with low visual-spatial abilities can benefit from well-directed animations.

PAPER PRESENTATION

The Circle of Change: Experienced Early Childhood Teachers as Graduate Students Who Became Leaders

Miriam Mevorach, Levinsky College of Education, Israel

The Circle of Change: Experienced Early Childhood Teachers as Graduate Students Who Became Educational Leaders

This paper explores perceptions of professional identity among experienced early childhood educators (ECEs) who are novice students in a new master's degree program in early childhood education. We seek to examine the changes experienced by these educators. The study used qualitative content analysis, which included two level procedures: a) at the beginning of the first year of the program the students were asked to write freely their definition and description of the role of an ECE. At the end of second year of the program the same participants were asked to define and describe once again their role perception; b) 8 students from the above group were interviewed in-depth narrative interviews at the end of the program. The findings indicate a change in the participants' perceptions of their multi-dimensional professional identity. They began to examine the early childhood educational system with a critical point of view based on their academic and pedagogical conceptual vision, and aware of the contingent political consequences. We believe this study will enable us to advance the early childhood education system and promote academic research conducted by professionals.

The Circle of Change: Experienced Early Childhood Teachers as Graduate Students Who Became Educational Leaders

The study examines the professional identity of graduate students who are professional and experienced early childhood educators (ECEs) and at the same time novice graduate students. This study is anchored in two points of view: a global perspective, finds expression in the importance that many countries worldwide attribute to early childhood education and, a local perspective, examines the local context, (most kindergarten classes -ages 4-6- in Israel operate as autonomous neighborhood institutions, and the kindergarten teachers are independent in terms of administration and management) and in particular the students studying in the ECE master's degree program.

We attempt to clarify how the combination of advanced studies and experience in education affects the possibilities for change in the early childhood educational system (Sammons, et al., 2005) by examining students' perceptions of their professional identity.

Experienced early childhood educators who decide to return to academic studies after many years of practice already have a formulated perception of their professional role, usually based upon beliefs accumulated during their professional careers (Fairbanks et al., 2010; Saracho & Spodak, 2006). We examined their role perceptions and changes in these perceptions from the beginning of the program to the end.

Method

The study is a qualitative research based on a phenomenological research tradition, aiming at pointing to the changes at experienced ECE, and narrative research, aiming at exposing their perceptions of change in their professional lives. The research participants included 36 students in the master's degree program in ECE. All the student participants hold B.Ed. degrees and are certified to teach early childhood education (birth to age 8).

Procedure

We conducted two level procedures: a) at the beginning of the first year of the program the students were asked to write freely their definition and description of the role of an ECE. At the end of second year of the program the same participants were asked to define and describe once again their role perception; b) 8 students from the above group were interviewed in-depth narrative interviews at the end of the program.

The interviewees were asked to tell their own professional "story of change". The interview model adhered to the narrative interview model of Libliech, Tuval-Mashiach, and Zilber (1998). The texts were analyzed by content analysis, as is common in qualitative research (Creswell, 1998). Researchers analyzed the texts independently and then compared notes until they reached agreement about the final categories. The categories were presented to the participants and they were asked to respond to the classifications. The agreements between the participants and researches were rather high.

Results

The first participants' written texts that were collected at the begging of their studies and were analyzed by content analysis, revealed two major domains: educational-pedagogical and organizational-managerial. Most of the references in the text as a whole were in the educational-pedagogical domain (32 students).

The most frequent category in the prevalent educational-pedagogical domain was concern for the children's wellbeing. The participants mentioned terms such as nurturing, creating, giving, providing "to create an atmosphere in which the children feel secure." They also spoke metaphorically in terms of "ground": "to cultivate safe ground for growth, development and learning" or "to create fertile ground for the children and an accepting and loving environment."

In the other domain, organizational-managerial, five categories emerged. The most frequent category represented the participants' efforts to cope with staff management in the kindergartens.

The second participants' written texts that were collected toward the end of their studies were analyzed at the same procedure as the first one. This time we found that the texts were for the most part planned and structured and that they reflected the writers' awareness of the structure and complexity of their role perception.

The findings revealed: a) a change in the frequency of utterances for all the categories; b) the addition of a new category – leadership – to the organizational-managerial domain; c) a marked reduction in utterances in the "preparing for life" category; and d) high frequency in the "management" category in the organizational-managerial domain. We identified three categories in the new domain of ecological systems. The most frequent category by far was the ecological system role.

The in-depth interviews provided us opportunity to illuminate participants self esteem change and their expanded role perception. Their discourse with themselves was rich, complicated, judgmental and critical.

For example one student pointed to her leadership abilities, her ability to carry everyone who comes to the kindergarten along with her. "Today, after studying and observing myself as an individual, I know that I am a leader. I lead the staff that works with me, the parents and the children. Not only do I manage the money and the reporting in the kindergarten, I am a leader who carries along the staff, the parents and the children."

In conclusion, the major findings representing the change in the participants' perception of their professional identity emerged in their multidimensional observations and their critical examination of their role, as well as their conscious ability to declare their importance as managers and educational leaders in the ECE system.

Discussion

The major finding, the change in the participants' perception of their professional identity, emerged in their multidimensional observations and their critical examination of their role perception as a bricolage (Kinchelone & McLaren, 2005) of their diverse responsibilities, as well as their conscious ability to declare their importance as managers and educational leaders in ECE (Muijs et al., 2004; Rodd, 2006). As a result, they became self-researchers capable of examining their practices as well their professional beliefs and thus promoting their confidence in their educational leadership within their multi-agent community (Genishi et al., 2001).

By the end of their studies, they realized that their professional discourse had changed and that they were now able to critically examine their ecological system (children, staff, parents. and community) (Bronfenbrenner, 2005).

These new abilities to crystallize their observation of explicit decision-making policies and to raise their voices to declare the need for improving the early childhood educational system have the potential to initiate new waves of actual change.

PAPER PRESENTATION

Is there a gap between teachers' conceptions and ICT competencies to teach in an online environment

Teresa Guasch, Universitat Oberta de Catalunya (UOC), Spain ; ANNA ESPASA, UNIVERSITAT OBERTA DE CATALUNYA, Spain

How many studies highlight the benefits of designing learner supports, as e-feedback, particularly in an online learning environment? As you may presume, there is a great number of authors who have studied educational supports in an environment based on written and asynchronous communication, as this context calls for specific teaching and learning competencies. Nevertheless, despite the evident need found in the literature, teachers' educational supports are not commonly used throughout the teaching and learning process in an online environment, but are usually only employed towards the end of the process. The aim of this research is to ascertain if the explicit lack of learner supports in an online teaching environment is due to the gap between teachers' conceptions and their ICT competencies to teach in this specific environment. A questionnaire was answered by 696 university teachers from a virtual university. The close correlation between conceptions of teaching and learning in a transmissive way and low competencies to teach in an online environment on the one hand, and the high level of competences shown by teachers within the profile of facilitators of learning on the other hand, clearly highlight the need to design specific teacher training proposals for an specific learning context based on written and asynchronous communication.

Theoretical approach and aims

How many studies highlight the benefits of designing learner supports, as e-feedback, particularly in an online learning environment? As you may presume, there is a great number of authors (i.e. Thorpe, 2002; McLoughlin, 2000; McLoughlin & Marshall, 2000; Coll, Engel & Bustos, 2009) who have studied educational supports in an environment based on written and asynchronous communication, as this context calls for specific teaching and learning competencies to teach (Guasch, Alvarez & Espasa, 2010). Nevertheless, despite the evident need found in the literature, teachers' educational supports are not commonly used throughout the teaching and learning process in an online environment, but are usually only employed towards the end of the process (Espasa & Meneses, 2010).

Following Thorpe (2002), learner support "refers to the meeting of needs that all learners have because they are central to high quality learning—guidance about course choice, preparatory diagnosis, study skills, access to group learning in seminars and tutorials, and so on". In particular, McLoughlin notes that educational supports in online environments should promote reflective thought and provide opportunities for interaction between teachers and students. McLoughlin and colleagues also understand that supports must be oriented to facilitate self-learning, self-evaluation by the student, flexibility to identify the learning strategy more appropriate to resolve each situation and should enable students to become aware of their own learning process. We consider that these supports do not differ from a face-to-face environment, but they ought to be considered specifically as we have already mentioned there is a lack in the practice.

This study has been designed with a view to address the discrepancy between what is expressed in the literature and the lack of evidences in the practice.

The aim of this research is to ascertain if the explicit lack of learner supports in an online teaching environment is due to the gap between teachers' conceptions of the same and their ICT competences to teach in this specific environment. Our hypothesis lies on the idea that there is an important group of teachers adhering to a transmission view of education because of their lack of competencies as an online educational professional (the teacher is often an expert in a field of knowledge, but not in didactic-pedagogic skills that allow them to know how to teach).

Methodology

The study was carried out at the Universitat Oberta de Catalunya. This university is a fully virtual university. The teaching and learning process takes place within virtual courses, and the communication is written and asynchronous. 696 university teachers from different disciplines (Economy, Law, Psychology, Computer Science, Education, and Politics) answered an online questionnaire. There were 303 females (43.53%) and 393 males (56.46%).

The questionnaire had two parts: 1) Teachers' conceptions: specific questions and different situations based on experiential learning theory. There were 14 items (e.g. "Virtual learning is mainly based on the students' independent work", "Students in a virtual environment are sufficiently self-organized") (Cronbach's $\alpha = .67$). These items were measured using a 5 point Likert scales (totally agree- totally disagree). 2) Teachers' competencies in teaching and learning in virtual environments. For this purpose, the competency framework defined in the European project Elene-TLC <http://www.tlcentre.net/competencyFramework.cgi> was adopted.

To assess the competencies two scales were adopted: a scale that measures planning with items like "To design guidelines to learn" (Cronbach's $\alpha = .740$) and a scale that measures development with items like "To promote collaboration among students" (Cronbach's $\alpha = .791$). There were 6 items per scale.

Findings and final remarks

Two teacher profiles were identified: a profile close to the transmission view of education, where "the student is autonomous on the learning process (teachers and/or peers' supports are not necessary to learn)" versus a profile where the "teacher is a facilitator of learning". These two profiles were distributed into four groups statistically different (cluster analysis) in relation to: teaching discipline, years of experience in a face-to-face environment, years of experience in an online environment, ICT competencies.

It was established that the teaching discipline influences both the conceptions and competencies teachers hold about teaching in an online learning environment.

There are also significant differences between teachers' conceptions about learner supports and their perceptions of their level of knowledge about the ICT available in the virtual campus. University teachers that consider themselves as having very high knowledge of teaching ICT are less identified with the profile of teacher as a transmitter of knowledge.

We consider that these results are relevant for the design of teacher training proposals with the aim to develop competencies to teach in online environments. The close correlation between conceptions of teaching and learning in a transmissive way and low competencies to teach in an online environment on the one hand, and the high level of competences shown by teachers within the profile of facilitators of learning on the other hand, clearly highlight the need to design specific teacher training proposals for an specific learning context (based on written and asynchronous communication).

PAPER PRESENTATION

How do students try to overcome academic procrastination? A qualitative interview-study

Justine Patrzek, University of Bielefeld, Germany; Carola Grunschel, Bielefeld University, Germany; Stefan Fries, University of Bielefeld, Germany

Academic procrastination (AP), the tendency to postpone study related tasks, is a prevalent phenomenon within the university context. AP may result in negative consequences and up to 60% of students wish to reduce their dilatory behaviour. Until now, little is known about what students actually undertake to reduce AP in their daily life. However, investigating this issue allows formulating ideas how to support students effectively in reducing AP. To address this question we conducted interviews with 24 highly procrastinating students concerning their efforts to overcome AP. Interestingly, the students mentioned starting points (what they want to change) and not only methods (how they want to change) for reducing AP. By conducting a qualitative content analysis a category system emerged in which we differentiated on the topmost level between starting points and methods. Further, we classified the mentioned starting points into five categories and 11 themes, like time-management (e.g. begin of work), self-regulation (e.g., distractibility), and circumstances (e.g., double burden). Additionally, six categories and 11 themes emerged for the methods, e.g., methods regarding time-management (e.g., writing to-do lists), behavioural (e.g., self-reinforcement) and cognitive methods (e.g., self-instruction). According to the students' statements, they use a variety of methods to overcome AP. However, they seem to neglect using more sophisticated methods concerning affects and cognitions. A problem of students procrastinating academic tasks could be that they know what they need to work on but do not know how to accomplish it. Implications for academic counselling and university teaching will be discussed.

Aims

Academic procrastination (AP) has been defined as "intentionally deferring or delaying work that must be completed" (Schraw, Wadkins, & Olafson, 2007, p. 13). Different studies showed that AP is a highly prevalent phenomenon among students (e.g., Solomon & Rothblum, 1984). Overall, AP can lead to negative consequences like stress and lower grades (Tice & Baumeister, 1999). Further, up to 60% of students report wishing to reduce AP (Solomon & Rothblum, 1984). As a result, many universities offer counselling for students supporting them to overcome their dilatory behaviour (e.g. Schouwenburg et al., 2004). However, until now little is known about students' own efforts to reduce their dilatory behaviour in their daily lives. In our study we aimed at investigating how students reduce their dilatory behaviour in their daily life. Exploring this perspective promises to result (1) in an inventory of the students' efforts to overcome AP and (2) thereby, in identifying implications for student counselling as well as for university teaching.

Method & Sample.

The students were recruited by announcements and by student counsellors at a German university. The recruitment resulted in interviews with 24 participants, 13 of which were female. On average, the students were 27.9 (SD = 6.3) years old and studied different subjects (e.g., sociology, biology). The students' mean study duration was 7.7 (SD = 6.6) semesters. In order to assure that the students were versant with AP their tendency to procrastinate was measured by the Tuckman Procrastination scale adapted to the academic context (Tuckman, 1991) and amounted to $M = 3.8$ ($SD = .5$). Procedure. The interviews were conducted by two of overall seven trained interviewers who kept to a standardised interview-outline. Within the interview the students were questioned about their experience with AP. In a first part of the interview students were to refer to reasons and consequences of AP to sensitise the students to the topic. In a second part they were asked whether they wish to reduce their dilatory behaviour and what they actually do to reduce it. The second part of the interview was analysed in order to encounter the above mentioned aims.

Analyses.

The interviews were transcribed and content-analysed (Mayring, 2000) by three coders. As qualitative content analysis is a rule-guided and structured process (Mayring, 2000), we performed the following steps: First, the interviews were segmented into 226 interview segments. Second, the coding was performed through an iterative process of deducing categories from existing literature and inducing categories from the interview content. A category system with 11 categories and 30 themes emerged. Third, the quality of the coding was investigated by calculating the inter-coder agreement, which was good (Fleiss' Kappa = .89).

Results

As the students did not mention only methods (how they reduce AP), but also potential starting points (what they want to change to reduce AP) for interventions, we differentiated between starting points and methods on the topmost level of the category system. On a second level we structured the students' statements concerning the starting points into five categories and 11 themes and concerning the methods into six categories and 19 themes. Regarding the starting points the students mentioned we differentiated between the following categories as well as themes: time-management (e.g., begin of work), self-regulation (e.g., distractibility), thoughts (e.g., beliefs), experience (e.g., feeling of success), and circumstances (e.g., double burden). An exemplary student's statement for the last theme is "[...] less double burden [...] would be good, but it all happens at the same time: university, working, leisure time". Concerning the methods the students mentioned we distinguished between methods regarding time-management (e.g., writing to-do lists), behavioural methods (e.g., self-reinforcement), cognitive methods (e.g., self-instructions), methods enhancing the knowledge about AP (e.g., reading self-help books), methods involving the social environment (e.g., working in teams), and methods relating to the study context (e.g., regular checking of standard of performance). An exemplary student's statement for the last mentioned theme is "I had to write a term paper and before I did this the lecturer offered an exam and I decided to take this exam so I could evaluate what I have already learnt [before starting to write]".

Theoretical and educational significance of the research

In sum, students did not only mention methods, but also starting points for potential interventions. The methods the students mentioned ranged from methods applying to their time-management to methods involving the social network (e.g. learning in groups). However, the students did not seem to know more sophisticated cognitive methods, like the ABC analysis, which could help them to reduce AP. Besides, they did not broach the issue of emotions and the importance to control them in the learning process. As the students' statements contained starting points for interventions as well as methods it can be speculated that some students seem to know what they could enhance concerning their learning process but do not know how to do it. The results of the study point to the need to enhance the students' knowledge about different methods for overcoming AP in daily lectures as well as in student counselling. Thereby, the students' learning efficacy could be fostered.

PAPER PRESENTATION

Learning from incidents in organisations

Dane Lukic, Glasgow Caledonian University, United Kingdom; Anoush Margaryan, Glasgow Caledonian University, United Kingdom; Allison Littlejohn, Glasgow Caledonian University, United Kingdom

Every organisation experience problematic situations not necessarily termed incidents. It is important to understand these situations and learn from them so that they do not reoccur or to draw points for novel problems that might arise. However there are different factors which might contribute to the effectiveness of the approaches to learning from incidents. The aim of this paper was to explore the factors that are important in choosing and developing approaches to learning from incidents in the safety context at two sites. The study surfaced five areas of importance which form a proposed framework for learning from incidents in organisations:

1. Learning context -Informal and formal learning.
2. Learning participants -inclusion and individual agency and represent the breadth of learning.
3. Type of incident– the relation between the complexity of the incident influence the learning approach employed
4. Type of knowledge- conceptual, procedural, dispositional and locative knowledge.
5. Learning processes- single or loop double learning processes are considered and represent the depth of learning.

Introduction

Every organisations experiences problematic situation, not necessarily termed incidents. It is important to understand these situations and learn from them so that they do not reoccur or to draw points for new problems that might arise. Organisations usually have less or more formalises approaches to learning from incidents (LFI). However there are different factors which might contribute to the effectiveness of these approaches. The aim of this paper was to explore the factors that are important in choosing and developing learning approaches in the safety context at two sites.

Method

37 interviews semi structured interviews were conducted at two large intentional energy sector companies. The sample was derived through a combination of stratified and convenience approaches where people at different levels of the organisation were included in the study to represent the variety of viewpoints. The participation was voluntary and interviewees were familiarised with the project. Interviews were transcribed and anonymised before analysis. The qualitative analysis included the FrameWork[i] approach where both individual case and thematic analysis can be conducted complimentary.

Theoretical framework

There were five areas of importance arising from the literature review and the data analysis. These 5 areas were underpinned by theoretical concepts which served as analytical lenses in analysing the qualitative data (Figure 1)

Figure 1. Framework for learning from incidents in organisation [Appendix image 1]

Formality of learning approaches represents considerations as to what degree the learning initiatives should be a part of formalise procedures, having in mind the characteristics of formal and informal learning. (Beckett & Hager, 2002)

For participants of learning it is necessary to understand who is to be included in the process of identifying solutions and to what extent they should participate in the learning process. Both individual and organisational aspects should be taken into account. Here the concept of inclusion and individual agency are of relevance (Billett & Pavolva, 2005).

Type of incidents represents the relation between the nature of the problems causing incidents is and the learning solutions. Cynefin framework provides an understanding through four areas of complexity used for sense making: 'simple' and 'complicated'- orderly domain; 'complex' and 'chaotic' -'un-orderly' domain. Problems may arise when solutions for orderly cases are applied to un-orderly incidents (Snowden, 2002)

Under the type of knowledge four types were discussed: conceptual, procedural, dispositional, and locative knowledge. Conceptual knowledge ("knowing why" and "knowing what") comprises facts, concepts and propositions (Anderson, 1982). Procedural knowledge ("knowing how") comprises techniques and skills that enable one to enact conceptual knowledge. Dispositions underpin conceptual and procedural knowledge and comprise attitudes, values, emotions, interests and personal motivations (Perkins et al, 1993). And lastly locative knowledge represent "knowing where" to find knowledge and information (Nicholls-Nixon, 1997).

Learning process was looked at through Argyris and Schon's theory of single and double loop learning (Argyris & Schön, 1996). In this context, single-loop learning includes solutions to errors and mishaps in the organisation by correcting the superficial elements of the problem. Double-loop learning is based on open inquiry into deep-rooted causes, system failures and values. The main obstacle for double-loop organisational learning is the 'win-lose' frame of thought and ego-protection as dominant features of organisational life.

Results

Formality of learning Our study indicated that the benefits of formal learning initiatives include structure and the number of people they can impact as well as perception of higher validity. Informal discussions and communication, although happening in a more spontaneous way, were deemed individual-specific and could be lost if a person changes position or leaves. It can be concluded that it is important to take the degree of formality of initiatives into consideration in developing approaches that would benefit from both the broad accessibility and verified nature of formal learning, as well as building on natural and open inquiry typical of informal learning.

Learning participants

The level of inclusion in learning approaches appeared to be fairly high at both sites. Interviewees ascribed high importance to the opportunity to participate fully in an LFI initiative. Therefore, employee individual agency was

deemed an essential component of learning from incidents and important in ensuring employees ownership of the safety processes and motivation for learning. However, the social aspect of agency and pathways for participation that an organisation opens was very relevant for the functioning of individual agency

Type of incident

Only full investigations managed to look into the relation of the nature of the problem and the learning approach undertaken. Moreover, they reported a tendency to condense the learning points into simplistic, 'bullet points' or one sentence long key learning points. Such oversimplification may result in the loss of deep contextual meaning and a limited transferability of learning points arising from an incident.

Type of knowledge

Our data indicates that the majority of the LFI initiatives address primarily conceptual and procedural knowledge. Locative knowledge was mainly reflected in informal communications. Dispositional knowledge does not seem to be considered by organisations when selecting a learning approach. LFI at both sites appears to focus primarily on rather decontextualised procedural and conceptual knowledge.

Learning process

Most learning initiatives displayed characteristics of single loop learning. The inconsistency of actions following an investigation was highlighted as particularly important by the respondents. Interviewees also highlighted the impact of ego-protection routines, and, consequently, pointed out lack of incentive to share openly information about small-scale events. However, the data also provided some examples of individuals exhibiting a level of inquiry by reflecting on the learning initiatives and also taking their concerns to those responsible for learning in their organisation.

Few of the initiatives at the sites examples addressed the five areas discovered through the study. The proposed framework encourages a holistic view of learning from incidents, in the context of the whole cycle of an incident. Moreover it promotes contextualised learning from safety incidents coupled with sense making and reflection, which were found to be lacking at the two sites. The findings could be relevant not only to the energy sector but also to learning from problematic situations in all organisations.

PAPER PRESENTATION

Diversity in teams

Regina Mulder, Universitaet Regensburg, Germany; Maria Rupprecht, University of Regensburg, Germany; Hans Gruber, University of Regensburg, Germany

Cooperation in teams is supposed to facilitate learning of individuals through knowledge exchange with colleagues about relevant topics. Consultancies try to organise and elaborate knowledge through teamwork. As a consequence of internationalisation, consultancies are challenged to operate at a global market. Consultancies thus are increasingly characterised by diversity in their social demographic, informational, and cognitive background. Diversity in teams can lead to more unconventional solutions, but can also increase misunderstandings and conflict. To deal with the problems of diversity and to exploit the potentials of diversity, consultants need to develop a common frame of reference (in our study: a team mental model TMM) and a common view of an ideal future state (in our study: a shared vision) within their team. Aim of this study is to answer the question: What is the relation between team learning behaviour, TMM/shared vision and innovative behaviour in diverse consulting teams? Data were collected in a survey (October 2009–January 2010) among 403 consultants of 110 European consulting teams that worked currently together on a project. Data were analysed on individual and team level (multi-level analyses). The results show that innovative behaviour was (1) positively related with team learning behaviour, (2) positively related with TMM/shared vision, (3) not significantly related with demographic diversity, (4) positively related with informational diversity, and (5) negatively related with cognitive diversity. This pattern of results has many implications for professional learning and work which will be discussed in the presentation.

Learning is no activity that occurs before one enters the workplace or separately from being engaged in productive activity; learning is the heart of productivity (Felstead, et al., 2005). Especially in consultancies, performance depends highly on the quality of knowledge of the consultants. Therefore, informal learning at the workplace plays a key role in

everyday work of consultants. As consultancies are under strain to be innovative, they try to organise knowledge through teams as informal learning settings. It is assumed that teams can better adapt to requirements of various situations and generate more creative strategies than individuals. As a consequence of internationalisation, consultancies are strongly affected by increasing diversity in the background of its employees. Research on team work and collective learning shows that it is not sufficient that individuals engage in creative processes. Information and accompanying learning processes must be transferred at the team level. To enable innovative team work, the consultants need to develop a common frame of reference defined as team mental model (TMM). A TMM is an organised, mental representation and shared understanding on key issues among its members (Klimoski & Mohammed, 1994). Similarly, a common view of an ideal future state can be defined as a shared vision. The development of TMM/shared vision is understood as a collaborative learning process. Demographic and informational diversity in teams can lead to cognitive diversity. Cognitive diversity can enlarge the available information (Van der Vegt & Janssen, 2003); however it can also lead to stereotypes involving negative effects on team performance. Research on diversity and innovation highlights the importance of team diversity to foster innovative performance. However, there are inconsistent results on diversity in teams and its positive or negative influence on innovative behaviour. Aim of this study is to answer the research question: What is the relation between team learning behaviour, TMM/shared vision and innovative behaviour in diverse consulting teams?

The hypotheses are:

- (1) Demographic diversity is negatively related with team learning behaviour, TMM/shared vision and innovative behaviour.
- (2) Informational diversity is positively related with team learning behaviour, TMM/shared vision and innovative behaviour.
- (3) Cognitive diversity is positively related with team learning behaviour, TMM/shared vision and innovative behaviour.

Sample

The sample comprised N=471 consultants of n=121 consulting teams from Germany, Austria and Switzerland that worked currently together on a project. 418 consultants (response rate: 88.8%) participated in the survey. Eleven teams with response of only one team member or a response rate below 50% were excluded from further analyses. A total of 403 consultants from 110 teams remained in the sample. A team consisted of at least two members.

Instrument

An online-questionnaire with a five-point Likert scale was developed. The questions comprised general information on the project, team, organisation, and team related context factors (team potency, team identification, task interdependence, individual differentiation) and the following scales: (1) team learning behaviour (knowledge development, reflective behaviour), (2) TMM/shared vision, (3) diversity (demographic, informational, cognitive), (4) innovative behaviour (teamwork behaviour during the idea generation, creative behaviour during the idea generation, activities during the idea promotion, activities during the idea realisation). The questionnaire was tested and refined in a pre-study.

Analysis

Descriptive statistics and correlations were computed. Based on a formula by Teachman (1980), a mean diversity index of demographic and informational diversity was calculated for each team. Furthermore, a within-group-agreement analysis rwg (James, Demaree, & Wolf, 1984) was computed for cognitive diversity to examine the appropriateness of aggregating individual ratings to team level. This within-group agreement analysis yielded a median value of .92. Given the hierarchical structure of the data, a multilevel analysis was conducted to decompose the total observed variance into individual-level and team-level residual variances and to examine intra-class correlations and within- and between-group variances.

Results

The intra-class correlations (ICC) for team potency (.12), team identification (.20), individual differentiation (.12), team learning behaviour (.35), TMM/shared vision (.30), cognitive diversity (.20), innovative behaviour: teamwork behaviour during the generation of ideas (.29), innovative behaviour: creative behaviour during the generation of ideas (.28), innovative behaviour: promotion of ideas (.27), and innovative behaviour: realisation of ideas (.18) show that the between-group differences were substantial. The ICC of zero for task interdependence indicates that task interdependence is not directly influenced by group-level predictors. ICCs of all aspects denote that differences within groups are larger than those between groups.

Team potency and team identification had positive relations with innovative behaviour, task interdependence has a positive relation with teamwork behaviour during the generation of ideas, the promotion of ideas and the realisation of ideas, individual differentiation had a negative effect on teamwork behaviour during the generation of ideas and the realisation of ideas. Team learning behaviour and TMM/shared vision had positive relations with innovative behaviour. Concerning diversity, differences in demographic attributes revealed no significant effects on innovative behaviour, differences in informational attributes showed a positive effect on creative behaviour during the generation of ideas and the promotion of ideas, and difference in cognitive attribute were negatively related to teamwork and creative behaviour during the generation of ideas, and the promotion of ideas.

Discussion

In knowledge intensive businesses diversity in the background of its members plays a minor role for professional learning and team work. More important for innovative work in projects seems the practised learning behaviour within the teams and the shared understanding on key issues among its members. Consequently, members of teams need to spend time on individual learning and engage in learning activities together with their colleagues in order to develop a common understanding within the team and thus to generate creative solutions.

PAPER PRESENTATION

Implementing supervised placement - reflections on the unity of a concept

Lars-Erik Nilsson, Kristianstad University, Sweden; Carola Aili, Kristianstad University, Sweden

Different forms of work-based learning have for a long time been considered important in academic programs. Some argue that it is the most important part in any vocational training, even in academic programs educating for professions. The aim of this paper is to discuss the variation in how work-based training is described and performed in different academic programs. Every year, for three years, heads of academic programs have been interviewed about their implementation of work-based training. The interviews have been conducted at a university that has placement in all programs. Curriculums, course plans and syllabus have been collected and analyzed. Our findings suggest that there are major differences in how to think "where education is good". Some programs have course plans where student placement is imbedded in progression through the program. Some programs "just place" students at the workplace or involve them in projects together with the organization where they are placed. Other programs have "theory driven" placement. Some programs have a placement organization that train staff to receive students while other programs leave it up to students to find a placement. We discuss the variation in viewpoints that can be found between programs-from the perspective of where education is good to think. How do different forms of placement relate to the ideas about what are the characteristics of a specific profession, to different ideas about education of professions and more general ideas about where it is best to learn?

A higher education, often carried out at universities, has been considered a hallmark of professions, one that lend legitimacy to claims to autonomy and jurisdiction over work tasks. Jurisdictions are since decades intimately associated with holdings of scientific knowledge (Abbott 1988). Collins (1979) has made the argument that science main importance is symbolic. The symbolic value of holding scientific knowledge obscures the fact that professional knowledge to a high degree has been acquired through processes of socialisation in work places (Collins, 1979). Svensson (1989) suggests that professionals' most important cultural capital consist of the ability to master the social practise of professional work where theories from the professions centre of knowledge transmission are being intertwined with experience into an inseparable whole. The act of educating professionals does not consist of setting up training programs alone, but involves choosing the appropriate forms for training. Whether controlled by professions, legal entities or market forces education involves choosing how to educate, what to incorporate in education and where to educate.

Our interest in this study concerns with reference to Levi-Strauss (1962, p. 128) but in our words "where education is good to think". This may seem far fetched since Levi-Strauss talked about what animals where good to think with for different tribes. The notion that academics can form tribes with their own symbolic capital to think with has gained some currency (Becher and Trowler, 2001). Whether this capital is primarily science based in higher education has been debated. Different forms of work-based learning have for a long time been considered important when learning a trade. Learning at work, when skills are passed from father to son, mother to daughter, experienced worker to inexperienced and more formally from master to apprentice present ways of representing "where education is good to think". Educating professionals can be considered to represent another way. Fransson (2009, p 22) argues that "professional autonomy in its traditional form requires a university with a position as exclusive and distanced in relation to other dominant social and cultural spheres". Today's academic programs, also hold other representations about "where education is good to think". Concept such as practice, internship, placement, work integration, clinical laboratories and business laboratories provide alternative representation. Some argue that these forms are the most important part in any vocational training, even in academic programs educating for professions and other occupations. Bridging theory and practice has in some quarters acquired a symbolic value.

One aim of this paper is to start a discussion about the variation in how work based training is described and performed in different academic programs. Every year, for three years, heads of academic programs have been interviewed about their implementation of work-based training. The interviews have been conducted at a university that have placement in all programs. Our interest has concerned a wide array of aspects from motives behind implementation of work-based learning to its part in the program, how examinations are carried out, how the program has organized placement and what contracts with receiving organizations involve. In addition curriculums, course plans and syllabus have been collected and analyzed for learning goals, methods of examination, assignments and supervision.

Our findings suggest that there are major differences in where heads of academic programs state that education is good to think. Some programs have course plan where student placement is imbedded in progression through the program. These programs have varied placements covering different aspects of students' future jobs. They may start with students observing moving on to them taking almost full responsibility. Some programs try to overcome the duality between theory and practice. They have "theory driven" placement. Students arrive at their placement with theories that they are required to use as they observe aspects of their work place. Some programs "just place" students at the workplace or involve them in projects together with the organization where they are placed. Some programs have assignments that they are assessed on. Other programs leave it to the supervisor at the work place to assess students. The differences in organization are vast. Some programs have a placement organization that train staff to receive students while other programs leave it up to students to find a placement for work based learning. Different programs have different ways of thinking good education. This includes where to educate. In the terms of Becher and Trowler (2001) they form different tribes with different ways of conceptualizing the good place for being educated. Work based learning in such a perspective seem to mean many things. We discuss this variation from four viewpoints. Differences that can be found between disciplines that dominate different programs. Diversity that can be found in what various types of professionals to be are expected to do during their supervised placement. The circumstances under which the program implement placement. How different forms of placement relate to different ideas about education of professions and more general ideas about where it is best to learn.

PAPER PRESENTATION

Towards reconceptualising professional agency at work from a subject-centred socio-cultural stance

Anneli Etelapelto, University of Jyväskylä, Finland; Paivi Hokka, University of Jyväskylä, Finland; Katja Vahasantanen, University of Jyväskylä, Finland; Susanna Paloniemi, University of Jyväskylä, Finland; Kaija Collin, University of Jyväskylä, Finland

The concept of agency has become widely used in working life research, especially in studies addressing workplace learning and creativity. However, there are various understandings of what the term actually means, and hence a need to elaborate how the concept is used within different theoretical frameworks. In this study we critically review recent notions of professional agency, and discuss how it can be reconceptualised from a subject-centred socio-cultural stance. We refer to literature from the social sciences and education, mentioning also approaches taken in gender studies and anthropology. We trace discussion on agency, and the ways in which discussion has moved towards understanding agency as related to the socio-cultural contexts of work communities, and as encompassing workplace practices, dominant discourses, power relations, and subject positions. In recent discussion on work-related learning, agency has been seen as closely related to professional identities. Agency is needed for reshaping

and renegotiating work identities. Moreover, subjects' sense of their professional self influences how they practise agency at work. In our conceptualising of professional agency it is understood as subjects' individual and collective capacity to make intentional choices, and to act on these choices in ways that will make a difference to their professional lives.

Aims

The concept of agency has become fairly widely used in working life research, especially in studies addressing workplace learning and creativity. However, there are various understandings of what the term actually means, and hence a need to elaborate how the concept is used within different theoretical frameworks. In this study we critically review recent notions of professional agency, and discuss how it can be reconceptualised from a subject-centred socio-cultural stance. In our discussion we selectively address those approaches which we consider relevant to research on professional learning and competence development at work.

Theoretical background

Based on a reading of scholarly literature and on prior research, we distinguish the following four notions, embodying different approaches to the concept of agency: i) the social science notion (Emirbauer, M. & Mische, 1998; Giddens, 1984), ii) the post-structural discursive notion (Fennwick & Somerville, 2006; Weedon, 1997; Wetherell, 2005), iii) the socio-cultural notion (Billett, 2006; Edwards, 2005; Holland et al, 1998; Wertsch, Tulviste & Hagstrom, 1993), and iv) the temporal life-course notions (Biesta & Tedder, 2007; Ecclestone, 2007; Elder, 2003; Emirbayer & Mische, 2007).. These approaches are widely used in multidisciplinary working life research, and we believe they can all contribute to an understanding of professional agency.

Research questions

The four notions are analysed in relation to the following questions: i) How do they define the relationships between the work context (structures) and working subjects (e.g. separated, autonomous, subjugated, interdependent, mutually interdependent)? And furthermore, what does this imply for the ontological understanding of human agency (individual/collective, power relations included/excluded, consideration given/not given to workplace practices, cultures, and dominant discourses)?

ii) What is the nature and degree of agency assigned to working subjects (e.g. agency as an option in choosing between at least between two alternative strategies of working; or agency as an option in influencing the power relations of the work community)?

iii) Is the intentionality of an action seen as a necessary condition for human agency? For example, is individual-level intentionality seen as a necessary condition for the practice of agency? Or is it sufficient if the action merely makes a difference to the subject's professional life, e.g. through collective changes?

iv) What kinds of manifestations of agency can there be, in terms of human actions (e.g. discursive, social, individually meaningful, embodied)? And how can these manifestations be captured by the methodological approaches applied?

v) How are the relationships between professional agency and professional identity understood? For example, is professional agency seen as closely intertwined with the subject's professional identity, and is agency seen as required for the reshaping and renegotiation of this identity? Or alternatively, is professional agency seen as separated from subjects' sense of their professional self?

Methodology

We refer to recent literature and to multidisciplinary research studies. Our discussion is derived from databases on working life research, where the focus has been on professional agency, work-related identities, professional learning, and competence development.

Findings

From a critical analysis of recent discussions in these domains, we put forward suggestions for a research agenda, with conclusions on how professional agency should be conceptualised in order to capture the relevant aspects of i) the authentic socio-cultural context, ii) the subjective side of the phenomenon, and iii) the mutually constitutive relationships between these two. From these starting points we conceptualise professional agency from a subject-centred socio-cultural perspective: we regard it as subjects' individual and collective capacity to make intentional choices, and to act on these choices in ways that will make a difference to their professional lives.

From our own empirical studies on professional agency we demonstrate how (in particular) narrative (Vähäsantanen & Eteläpelto, 2009; Vähäsantanen, Saarinen & Eteläpelto, 2010), discursive (Häkkinä, Eteläpelto & Rasku-Puttonen, 2009), and ethnographic research strategies (Collin, Paloniemi & Mecklin, 2010) can grasp different aspects of professional agency, encompassing the socio-cultural conditions of the workplace and subjects' professional identities.

Practical and theoretical significance

Based on our findings, we emphasise the need to investigate tools for the promotion of professional agency at work. We suggest that researchers on workplace learning should have a more active role in the research-based development of educational interventions aimed at promoting professional agency at work. Two kinds of interventions are seen as promising in this regard, especially in boundary-crossing situations, and in inter-professional work. These are complementary to each other and include a) the work conference and democratic dialogue method suggested by Gustafsen (1992); and b) the identity workshop, utilising narrative methods (e.g. Hänninen & Eteläpelto, 2008). We further draw practical conclusions regarding the promotion of professional agency, where the aim is to develop professional learning, competence, and creativity in organisational and working life.

PAPER PRESENTATION

Intended Learning Outcomes as a tool for university teachers learning

Linda Barman, Karolinska Institutet, Sweden; Charlotte Silen, Karolinska Institutet, Sweden; Klara Bolander Laksov, Karolinska Institutet, Sweden

Due to the Bologna declaration Sweden introduced new governmental regulations for Higher Education. This meant a shift towards outcome based education and requirements for teachers to formulate intended learning outcomes. In relation to the reform we have studied how teachers at a medical and health university reason about teaching and learning and how they approached the new outcome based curricula. We made a content analysis of course documents from 14 courses within different educational programs to capture changes between the last and the first course before and after the reform. After the second course round, we interviewed Course Directors responsible for designing the courses. We use a hermeneutic approach to analyse the interviews.

The preliminary findings show that teachers have high expectations of students' understanding of the ILO's and how ILO's may help students learning process. For most teachers in our study, the reform meant going from tacit objectives of what a course would give, to become more explicit expressing learning outcomes. Some teachers have taken on a more elaborated approach and involve students actively in discussions of what the learning outcomes mean and how to become more self-directed in their learning. However, constructing intended learning outcomes seem to facilitate teachers own learning foremost.

Background, Aims and Methodology

Due to the European collaboration within the higher education area, Sweden introduced new governmental regulations for higher education in 2007. The reform meant a shift towards outcome based education with a supposedly stronger emphasis on student learning (SFS 2006:1053; Weurlander, 2006).

A core feature of outcome based education is the emphasis on learning outcomes rather than process. According to Harden (1999) the communication of intended learning outcomes provides a clear framework for students to guide and encourage self-directed learning. Thereby teachers and students get a shared responsibility for learning (Harden, 1999).

At Karolinska Institutet, a university with a wide range of medical and health education, teachers were required to formulate intended learning outcomes. Leaning on the model of Constructive Alignment by Biggs (1996), the new policy included recommendations for alignment in course design, expressed through formal course documents (Weurlander, 2006). Formulating Intended Learning Outcomes (ILO's) requires teachers to be explicit with how

students should use the knowledge, skills and attitudes they learn from each course, e.g. to be able to perform a certain test or to communicate with patients in a defined context.

In relation to the reform we have studied how teachers from 14 different educational programmes at Karolinska Institutet reason about teaching and learning and what changes they performed in practice. The purpose of the study was to understand how policy may influence university teachers' ways of practice and their understanding about teaching and learning. In this study, teaching practice is represented by course design, e.g. what forms of assessments and learning activities that are planned. Teachers included in the study all had a role as Course Director with responsibility to plan the course. We made a purposeful sampling; one criterion was to get a variety of courses given within the university campus and within the health organizations.

To study differences in course design, course documents were gathered from the same course given both before and after the new regulations were implemented. After the second course round was finished, semi-structured interviews were held with the 14 teachers. An hermeneutic approach (Ricoeur, 1993) is used to analyse the interviews in order to understand how teachers may have changed or developed their reasoning about teaching and learning in general, but also how they come to understand and approach the new regulations with an emphasis on outcome based education. The course documents have been analysed with a thematic content analysis (Graneheim & Lundman, 2004) to capture the changes in course design before and after the new regulations.

Preliminary findings

For several teachers in our study, constructing the ILO's made them reflect upon, reason and together with other teachers discuss "what learning really means" and how learning may be assessed. As a consequence changes of the assessment methods were made towards more divergent assessments (Torrance & Pryor, 2001). Teachers used open questions where students have the possibilities to express what they know and understand instead of showing a predefined correct answer to a larger extent. Constructing the ILO's had become a mean for teachers' development of understanding more about learning.

In the interviews teachers refer to ILO's as "useful controllers" for course design. ILO's were used in an iterative process as a "marker" and gave clearance towards the teachers themselves of what the course was really about. Making the ILO's explicit made teachers change course content, learning activities and assessments to various degrees.

The ILO's were explicitly used by most teachers in the study to communicate the essence of the course towards different stakeholders. As many teachers put a lot of effort in the construction of ILO's, the teachers had hopes that this would help students in their studies. Teachers express high expectations of the students' understanding of the ILO's.

For most teachers in our study, the reform meant going from tacit objectives or aims of what a course would give, to be more explicit of student learning outcomes. However teachers also reflect upon the need to share and discuss the meaning of the ILO's and what it means for students own learning, together with the students. To explain this development we will use the framework suggested by O'Donovan et al. (2008) put forward to illustrate approaches to developing student understanding of assessment standards. The framework illustrates a movement from informal activities and inputs with passive student engagement onto formal activities and inputs with active student engagement.

Within the courses we studied, we find examples where efforts were made by teachers to get students more actively involved in understanding the ILO's and become more empowered in their own learning process. However the most existing change was going from tacit aims to explicit articulated ILO's that were passively presented to students. ILO's may be used as a "technical tool" for course design without adopting a social constructivist approach towards teaching and learning. Though, the collaborative construction of intended learning outcomes, seem to have facilitated teachers own learning about teaching and learning.

PAPER PRESENTATION

The effect of instruction of control on perception of control.

Mieke Vandewaetere, University of Leuven - Campus Kortrijk, Belgium; Geraldine Clarebout, University of Leuven, Belgium

Learner control as instructional technique is not equally effective for all learners. Three conditions are assumed to play a role in the effectiveness of learner control: the learners' skills, the learners' perceptions and the cognitive load that is experienced by learners. This study investigates the effect of instruction of learner control on learning outcomes, mental effort and motivation, by comparing learners that received additional instructions on learner control with a group of learners that did not receive additional instructions. Self-regulated learning skills and working memory capacity are incorporated in the model. Results show that simply offering instruction of learner control is not enough to affect motivation, mental effort ratings and learning outcomes. One reason for this might be that instruction as such does not suffice, and that additional support or advice is necessary for learners in order to deal with LC.

Introduction

Learner control (LC) is an instructional technique that can be considered as an opportunity to improve learning. However, learners do not always grasp the opportunities they are offered (Perkins, 1985). Corbalan, Kester, and van Merriënboer (2009) defined three conditions that should be met for an effective use of LC. Firstly, learners must have the necessary skills to deal with LC. LC is also strongly interwoven with prior knowledge (Williams, 1996), self-regulation (SR) and motivation (Kinzie, 1990). The interaction pattern between SR and LC was also demonstrated in that learners with low SR skills perform better when they are in a condition with program control, compared to a LC condition (Eom & Reiser, 2000; Winters, Greene, & Costich, 2008).

A second condition is that LC must be perceived by the learners. Empirical research has demonstrated the importance of perception of LC (Cordova & Lepper, 1996). Even though the offered choices are illusory or seem trivial, choice becomes meaningful if the learner experiences it as such (Katz & Assor, 2007).

Finally, there is the assumption that LC demands free cognitive resources since it posits an additional load on cognitive processing. Makany et al. (2007) demonstrated that, as learner control (in terms of navigational control in a hypermedia environment) required more cognitive resources, short term learning performances decreased.

To conclude, rather than the questions whether or not to provide LC, it is more important to support learners in maximizing the use of available LC (Merrill, 1984)

This research

The aim of this study is to shed light on the mechanisms behind the three conditions mentioned by Corbalan et al. (2009). We want to sketch (1) the role of self-regulated learning (SR; condition 1: learners need to have the necessary skills to deal with LC), the effect of instruction (condition 2: LC must be perceived by the learners) and model the relation between LC and cognitive load, as measured by working memory capacity (WMC; condition 3: LC demands free cognitive resources).

Method

All 156 participants were first year Educational Sciences students. Prior to the experiment we assessed prior knowledge, self-regulated learning skills (SRQL; Black & Deci, 2000) and WMC (GOSPAN; De Neys, d'Ydewalle, Schaeken, & Vos, 2002). Participants were randomly assigned to one of the three conditions: (1) no control, in which participants had to complete 40 preselected exercises on English tenses; (2) LC without additional instruction, in which participants had to complete 40 exercises on English tenses, but they could freely choose 40 exercises out of 102

based on their interests or learning goals; (3) LC with additional instruction, similar to condition two, but with additional instruction of LC.

After the experiment, we assessed the mental effort participants had invested in completing the exercises (mental effort rating scale; Paas, Tuovinen, Tabbers, & Van Gerven, 2003) and all participants completed the post-experimental motivation inventory (IMI; McAuley, Duncan, & Tammen, 1987). Other dependent variables are learning outcomes as defined by course score and posttest score.

The experiment was administered by using Moodle[™], wherein 102 exercises were created on English tenses. Exercises were labeled according to their difficulty level, their theme (the tense), and type (multiple choice, translation or fill-in).

Results

For all analyses, the significance level was set to .05. Pre and posttest questionnaires showed good to very good reliability statistics, with Cronbach's α ranging from $\alpha = .75$ to $\alpha = .93$.

Participants in different conditions were equal concerning their prior motivation, prior knowledge, WMC and SR skills. All analyses were done with following variables in the model: prior knowledge score, WMC score, SR skills and condition (no control, LC, LC with instruction).

Mental effort ratings. SR skills show significant effects on mental effort ratings ($F(1,144) = 13.39$, $p = .001$, $\eta^2 = .09$). The lower the SR skills, the higher the invested mental effort reported ($b = -.05$). There were no significant effects of condition ($F(2,144) = .25$, $p > .05$) and prior knowledge ($F(1,144) = 2.54$, $p > .05$). Also, working memory capacity ($F(1,144) = 1.35$, $p > .05$) did not show any significant effects.

Post-experimental motivation. Both prior knowledge ($F(1,136) = 4.74$, $p = .03$, $\eta^2 = .03$) and SR skills ($F(1,136) = 7.89$, $p = .006$, $\eta^2 = .06$) significantly affected motivation, although this effect was not related to the condition ($F(2,136) = 1.76$, $p > .05$) and WMC ($F(1,136) = 0.61$, $p > .05$). The higher the prior knowledge ($b = 1.67$) and the higher the self-regulated learning skills ($b = 0.54$), the higher the post-experimental motivation.

Learning outcomes. Prior knowledge (Wilk's Λ , $F(2,141) = 3.05$, $p = .05$, $\eta^2 = .04$) and self-regulated learning skills (Wilk's Λ , $F(2,141) = 6.10$, $p = .003$, $\eta^2 = .08$) significantly affected learning outcomes (as defined by course score and posttest score). The higher the self-regulated learning skills and prior knowledge, the higher the course and posttest score.

Discussion and Conclusion

Research on LC should not focus on whether to include LC, but rather on how to include LC, how to support learners in using LC (Merrill, 1984) and under which conditions LC gains the effectiveness of learning. In this study, we emphasized the importance of perception of LC and its effects on motivation, learning outcomes and mental effort.

We did not find any effect of instruction of LC on the dependent variables, nor did we find interaction effects between WMC, SR skills and instruction. This might be due to the lack of available support or advisement for the learners. Hannafin (1984) stated that learner control, compared to program control, is likely to be most effective in conditions where learner control is accompanied by advisement to assist learners in making appropriate decisions. Clarebout and Elen (2006) also stressed the importance of advisement and support in their research on tool use. Simply giving control to the learners is not enough. Simply instructing learners that they have control is also not sufficient. A follow-up study will be administered to see whether the combination of instruction and advisement on LC shows better results than simple instruction of LC.

PAPER PRESENTATION

Using process data to re-examine the hypothesized impact of relevance instructions on text-based learning

Lai Jiang, Institute Tropical Medicine/Katholieke Universiteit Leuven, Belgium; Jan Elen, Katholieke Universiteit Leuven, Belgium

The instructional effectiveness of relevance instructions (learning goals and postquestions) on factual learning and problem solving in a prose learning environment were examined. The difference with previous studies is that this study not only examined the learning outcomes, but more importantly, the learning process. This was done by investigating how students perceived and used the learning goals or postquestions and how they were engaged in learning processes with these instructional supports. The investigation of the process included examining students' interpretations of the learning goals, information selection and integration processes and monitoring behaviour. A

total of 110 university students studied a scientific text on the relation between obesity and impulsivity. They were assigned to a control group, a learning goal group or a postquestion group. Analysis of students' reading behaviour and cognitive processes suggests that the absence of significant performance differences between the conditions can be explained by referring to students' actual use of learning goals or postquestions.

Relevance instructions intend to help students in generating learning goals, allocate resources in a more systematic way and hence facilitate students to learn more efficiently from texts (McCrudden & Schraw, 2010). Relevance instructions can be learning objectives/learning goals, advance organizers or inserted questions. Although relevance instructions are intended to support learning, they do not always lead to better learning (e.g., Duchastel & Merrill, 1973; Reynolds, Trathen, Sawyer, & Shepard, 1993). The reported inconsistent effects of relevance instructions may be due to the ignorance of the variance in processes (i.e., learners' different use of relevance instructions)(Winne, 1982).

The increasing integration of education and technology provides opportunities to record multiple sources of data and to directly observe students' learning behaviour and cognitive processes (Hadwin & Winne, 2001). The current study investigated how relevance instructions were actually used in a prose learning environment. Log-file data that directly described students' cognitive processes and cognitive products was used to test the hypothesized links between two types of relevance instructions (i.e., learning goals and massed postquestions), cognitive processes and learning outcomes (e.g., Andre, 1979; Mayer, 1987; McCrudden & Schraw, 2010; Pressley, 2002).

Theoretical Hypotheses on the Facilitating Effects of Learning Goals and Postquestions

The intention of providing explicit learning goals (objectives) and postquestions to students is to cue and/or encourage them to cognitively operate on relevant information in a particular way (e.g., Salmeron, Kintsch, & Kintsch, 2010). The following theoretical hypotheses on the facilitating effect of learning goals and postquestions were tested in this study:

Hypothesis 1: Learning goals may help students to understand task demands and to set goals for studying (e.g., McCrudden & Schraw, 2007).

Hypothesis 2: Learning goals may help students to select relevant information (e.g., Lorch, Lorch, & Mogan, 1987) and

Hypothesis 3: Learning goals may help students to monitor their learning in a more systematic way (e.g., Duchastel & Merrill, 1973).

Hypothesis 4: postquestions may direct students reading attention (i.e., specific backward review and general backward review: Rickards, 1979).

Hypothesis 5: postquestions may stimulate students to monitor their reading comprehension (Garner & Reis, 1981) and improve the accuracy of students' self-monitoring during reading (Pressley, Snyder, Levin, Murray, & Ghatala, 1987).

Method

Materials

A program, called OBESITAS, provided a computer-based prose environment in which participants were asked to study a scientific text on the relation between overweight and impulsivity. The text comprises 2,178 words (17 paragraphs). Each paragraph was displayed on a separate screen.

Participants and procedure

One hundred and ten university students were pre-tested one week before the experiment. The results of the pretest were used to equally assign higher/lower prior knowledge students into three conditions: with learning goals (n = 37); with postquestions (n = 37) and a control group (n = 35). Students in the learning goal condition were asked to interpret the assigned learning goals and specify their learning objectives based on the assigned goals before reading the text. In the question condition, when students had read all the paragraphs at least once, postquestions appeared which had to be answered. Students' interpretations/answers were allowed to be modified at any time. A note space was provided in the three conditions. Students' notes were recorded and used to find out whether they carried out the intended cognitive processes. During the learning session, all learning behaviours and inputs of each participant were recorded in individual logfiles. Finally, a post-test was conducted to measure participants' factual knowledge, understanding of the relations between causal factors for obesity and the ability to solve problems.

Measure of cognitive processes and cognitive products

The following variables were recorded in logfiles and used to assess students' cognitive processes and cognitive products: students' responses to learning goals (to test hypothesis 1), notes in learning goal condition (to test hypothesis 2), answers to the postquestions (to test hypothesis 4) and studying sequence (to test hypothesis 3 & 5).

The analyses of students' studying sequence intended to find out whether students used learning goals/postquestions to monitor their cognitive actions and to adjust their studying processes when necessary.

Results

Students' actual use of learning goals and postquestions related to their theoretical hypotheses

H1: Not all students understood task demands and set specific goals in line with the assigned learning goals. For instance, for each learning goal, about 10 students failed to specify what they needed to do in order to achieve their own goals.

H2: Learning goals helped students to select relevant information. The analysis of the notes made by students in the learning goals condition were more strongly correlated to performance than the notes in the control condition.

H3, H4 & H5: Most students did not use learning goals or postquestions to monitor their learning in a more systematic way. Logfiles revealed that 64.9% of the students never reviewed goals after constructing their responses to them and only 6 out of 37 students realized that the information in their notes and their memory was not adequate and selectively reviewed the text.

Students' use of relevance instructions and performance

When comparing performance between three conditions, no significant difference was found. However, when looking at the relation between students' study behaviour and performance, strong relations were found. Students in the learning goal condition who understood the assigned learning goals correctly and described the goals in great detail achieved higher posttest scores. Furthermore, the higher the quality of notes (the better they implemented these assigned goals), the better they performed in the posttest. In addition, students who answered postquestions with backward review achieved better.

Conclusions

This study examined the hypothesized effects of learning goals and postquestions on students' learning processes and learning outcomes. A detailed analysis of students' behaviour and cognitive processes showed that students did not successfully carry out most desired cognitive processes. This could be the main reason for the lack of effects of learning goals and postquestions on intentional learning.

The results of the analysis of students' use of learning goals and postquestions at a behavioural and cognitive level provide evidence that the way in which instructions are used accounts for their instructional effectiveness. The detailed descriptions of students' interaction with learning goals/postquestions provide a sense of how commonly implemented instructions are actually perceived and used by students for knowledge acquisition. By looking deeply into the students' cognitive operations, this study identified specific suboptimal usage behaviour and therefore provides a better view for instructional designers on what needs to be done to tackle suboptimal use.

PAPER PRESENTATION

Does Animation Facilitate Comprehension of Public Information Graphics? Evidence from Eye Tracking

Jean-Michel Boucheix, University of Dijon, LEAD-CNRS, France; Jonathan Groff, INRETS & LEAD-CNRS, France; Richard Lowe, School of Education, Curtin University, Australia; Laurence Paire-Ficout, INRETS, Lyon-Bron, France; Stephane Argon, LEAD-CNRS, France; Laurent Saby, CERTU, France; Aline Alauzet, INRETS, Lyon-Bron, France

Graphic information displays have the potential to communicate public information in situations where normal announcement types are ineffective. This study used eye tracking techniques to analyze comprehension mechanism of event-related information on railway traffic disruptions presented via different graphic formats. One hundred thirteen participants were asked to understand and compare series of traffic disruption messages delivered via three purely visual formats. Animated displays were the most effective presentation type. Eye tracking data showed why an animation facilitates comprehension: it enhances processing strategies which provide the best condition for segmenting the causal chain of the events provided in the message.

Most previous research on the comprehension of animated graphics has concerned formal learning in scientific and technical domains (Bernay & Béêttrancourt, 2009; Hßffler & Leutner, 2007; Scheiter & al., 2010). This paper focuses on a rather different application of animations - providing public information messages about train traffic disruptions for people who cannot hear or understand normal spoken announcements. The target audience includes not only the

elderly, people with hearing impairments, and travelers from other countries, but also anyone else to whom loudspeaker announcements are 'unavailable' because of noise in the station or their distance from loudspeakers. Station loudspeaker announcements typically follow a standard event-based format such as: "Your attention please, contrary to the information that has been displayed, the TGV number 1259 for Paris, will not start from platform A but will start from platform B". Because travel disruptions can be a part of the everyday context for people taking trains, visual alternatives to spoken announcements (e.g. Figure 1) are one possibility for improving information availability. The approach taken in the present research study recruits theoretical ideas about visual comprehension from the Animation Processing Model (Lowe & Boucheix, 2008). It explores the potential of dynamic visual displays to quickly and effectively trigger a task-appropriate script of the relevant events. A key issue in using visualizations for this purpose is the extent to which bottom-up features of the external depiction map to top-down aspects of existing internal representations. Pilot investigations (Boucheix et al., 2010) with small samples of hearing impaired and elderly people suggested that comprehension could be higher with animated rather than static graphics.

The 113 undergraduate student's participants were randomly assigned to six groups, one for each version. Participants were presented with the disruption messages in their assigned format then asked to give verbal explanations of the message's meaning (i.e., what does it say, and what would you have to do in this situation). Eye movement (Tobii 120 hertz) and verbalizations were recorded and synchronized. Explanations were scored with a comprehension grid (interrater agreement, chance corrected Cohen's kappa, was 0.95), and the frequency of train travel recorded. Four Areas Of Interest (AOI) for the eye-tracking measures were based the area of on each picture (figure 2) and used to investigate processing behaviour (analysis included time to first fixation in each AOI, fixation duration, scan path and transition between AOIs).

Figures 3 shows comprehension scores (% for all messages). A repeated measure ANOVA (format x linearity x messages) showed a main effect of format $F(2, 107) = 5.81, p$ Figure 4 shows comprehension scores as a function of the frequency of train travel. A repeated measure ANOVA (frequency x message) showed a main effect of the frequency of use of trains on comprehension scores, $F(1, 111) = 32.51, p$ Eye tracking measures Due to space limitations in this summary, we include results here for only the first measure (time to first fixation on each AOI), Figure 5. A repeated measure ANOVA (Format x AOI) for all messages showed a main effect of the format $F(2, 654) = 46.14, p$

Findings from the present study indicate that animated graphics have the potential not only to facilitate public information comprehension but also to elicit more efficient information processing strategies. The animation format, seems to provide the best condition for segmenting the causal chain of the events provided in the message to facilitate comprehension.

PAPER PRESENTATION

Increase effectiveness of simulation-based learning through scripted collaboration

Florian Pilz, Ludwig-Maximilians-University Munich, Germany; Karsten Stegmann, University of Landau, Germany; Matthias Siebeck, University of Munich, Germany; Frank Fischer, Universität München, Germany

Simulations with standardized patients can foster knowledge acquisition in medical education. Often only one student can perform such simulations at a time. Offering students to observe the simulation and perform peer-feedback might enhance the effectiveness of the simulation. Because groups often work ineffectively collaboration scripts were used as instructional approach to support the learners. In a study with 235 medical students we varied an observation script (with vs. without), a feedback script (with vs. without) and the role during the simulation (examiner vs. observer). We examined the effects on the knowledge acquisition regarding the rectal exam. The observation script specified a list of important features the observer should focus on. The feedback script provided guidelines how to provide helpful feedback. The learning phase was segmented into three phases: First, the student in the examiner role performed the rectal exam while being observed by the observer. Second, while the examiner receives feedback from the standardised patient, the observer prepared feedback for the examiner. Finally, the examiner received feedback from the observer. Results show that the observation script (but not the feedback script) had a positive effect on knowledge acquisition for both roles whereas the observer benefitted significantly more. This study shows that the scripted observation of simulations can enhance the knowledge acquisition of learners.

Simulations with standardised patients can be an effective means to foster knowledge acquisition in medical education (cf. Schwald et al., 2009). However, usually only one student at a time can perform such simulation as examiner. By allowing other students to observe a simulation, the effectiveness of simulations may increase (cf. Zottmann et al., 2006). Not only the observer may learn from the social modelling and may reflect and modify their own knowledge by comparing themselves with the model (cf. King, 2007). In addition, the examiner may benefit from the observer's feedback. Feedback has been broadly found to be an effective means on knowledge acquisition (cf. Hattie, & Timperley, 2007). The most effective feedback is correct and provided in an informative and elaborated way (Hattie, 2009). However, peer-feedback often lacks certain qualities and needs to be supported (Hattie, 2009). Collaboration scripts can be regarded as an effective means to support specific collaborative learning activities (cf. Kollar et al., 2006). Collaboration scripts provide structures with respect to content (guidance through important steps) and with respect to interaction (support how to work together on a task) (cf. Weinberger et al., 2005).

Against this background our research question was, to what extent a content-related observation script, an interaction-related feedback script the role during the simulation and the interactions thereof affect the knowledge acquisition while learning with simulations in medical education.

Method

In a 2x2x2 pre-post design we varied an observation script (without vs. with), a feedback script (without vs. with) and the role (examiner vs. observer) during the simulation of a rectal examination. 235 medical students at the LMU Munich were randomly assigned to one of the 6 conditions. Learners participated in the learning session in dyads and took over either of the two roles. The learning session (about 45 minutes) was segmented into 3 phases: First, the student in the examiner role performed the rectal exam (about 20 minutes) observed by the second student. Second, while the examiner received feedback from the standardised patient (about 10 minutes), the observer prepared feedback for the examiner. Finally, the examiner received feedback from the observer (about 15 minutes).

The observation script specified a list of important steps the observer should focus on and asked the observer to check whether the examiner performed these steps. Without the observation script, observers were only asked to observe the examination and to provide feedback to the examiner afterwards. The feedback script asked the observer to pre-structure the feedback, to provide elaborated feedback including suggestions how to perform better and to ask the examiner to reflect on his/ her own performance. Without script, observers were only asked to prepare and provide feedback based on their observation.

The knowledge regarding how to perform a digital rectal exam was measured before and after the learning session. An expert solution differentiated 55 different relevant features of the rectal exam including communication aspects

(e.g., call the patient by name, announce the next steps) as well as medical content knowledge (e.g., inspection of the anal region, medication history). Two trained coders (Cohen's Kappa = .93) analysed the knowledge test regarding these features. The number of different relevant features in the description was used as measure of knowledge regarding the rectal exam.

Results

The observation script had a significant effect on the acquisition of knowledge. Dyads supported by the observation script showed higher knowledge gains than groups without script. Additionally there is a differential effect of the two roles. Both roles benefitted significantly from the observation script, however, the observer had significantly higher knowledge gains. The feedback script had no significant influence on the students' knowledge.

Conclusions

In line with the findings of Zottmann and colleagues (2006), our results show that observing a simulation can facilitate the acquisition of knowledge, but only if supported by an observation script. Furthermore, our results show that both roles benefitted from the observation script although the examiner had not worked directly with it. The examiner might benefit indirectly through enhanced feedback. Thereby, the effectiveness of the simulation was not only increased by the means of more participants per simulation, but also by the means of increased knowledge acquisition compared to individual learners. An important limitation of the study is that it was not measured how the students really perform a rectal exam. A performance-oriented post-test might show a better performance by the examiner than by the observer.

PAPER PRESENTATION

Boundary as bridge: A systematic conceptual review of the educational neuroscience literature

Catherine Beauchamp, Bishop's University, Canada; Miriam Beauchamp, University of Montreal, Canada

Recognizing the need to establish a connection between the findings of neuroscience research and teaching and learning contexts, this paper reports on a systematic conceptual review of 87 articles in the educational neuroscience literature focused on the link between education and neuroscience. This review, conducted by a neuroscientist and an educator, considers the problems of integrating two complex fields in the context of disciplinary boundaries and focuses on the following question: According to relevant literature, does educational neuroscience represent a bridge or a boundary for the merging of the two disciplines? The review resulted in an identification of themes related not only to tensions at the disciplinary boundary between the two fields but also to potential paths for resolving these tensions. It suggests that using the lens of disciplinary boundaries has potential for enhancing an understanding of the emergent field of educational neuroscience.

Aims:

The need to establish a connection between the findings of neuroscience research and teaching and learning contexts is documented in both neuroscience and education literature (e.g., Ansari, 2008; Goswami, 2004). The emergent discipline of educational neuroscience aims at “the integration of the diverse disciplines that investigate human learning and development ... to form the new field of mind, brain and education” (Fischer et al., 2007, p.1). However, concerns exist that the impact of neuroscience research on education has been less effective than hoped and further efforts are required to strengthen the connections between the two disciplines (Willingham, 2009). Bruer (1997) suggests that the linking of the two disciplines may be “a bridge too far”; others comment on the notion of a bridging of the two in both positive and negative ways (Willis, 2008). In seeking a way forward, it may be useful to consider the problems of integrating two complex fields in the context of disciplinary boundaries (Akkerman & Bakker, 2009). Evidence indicates that different disciplines remain entrenched in their traditional cultures, hindering a smooth crossing from one to another or a blending of two or more (Becher, 1989). Yet Dillon (2008) has noted that the idea of boundary crossing has potential for examining transactions that take place at the boundary between disciplines. While the notion of boundaries has been prevalent in the transfer from one social context to another (e.g. from an academic to a workplace setting) (Tuomi-Grohn & Engestrom, 2003), it may also help take into account the tensions generated by the integration of multiple disciplines (Dillon, 2008). As a neuroscientist and an educator, our aim was to understand the potential links between neuroscience and education by using boundaries as a lens for a systematic review of educational neuroscience literature and to extract common tensions and promising insights. We focused on the following question: According to the relevant literature, does educational neuroscience represent a bridge or a boundary for the merging of the disciplines of education and neuroscience?

Methodology:

We systematically reviewed literature in PsycInfo, ERIC, Medline and Current Contents (1970-2010) for empirical articles, conceptual papers, and commentaries in the field of educational neuroscience using these keywords: education, teaching, classroom(s), and pedagogy combined with neuroscience, brain, neuromyth(s), as well as the overlapping terms ‘educational neuroscience’, ‘mind, brain and education’, and ‘neuroeducation’. 467 references were categorized into four areas, one representing 87 articles whose central focus was the linking of education and neuroscience. We categorized the contents of these articles according to themes of boundary language, inter-disciplinary tensions, needs at the boundary, and potential aids to resolving tensions.

Findings:

Although none of the reviewed works referred directly to boundary theory, recurring vocabulary suggests indirect use of boundary principles, including the idea of connections and bridges between disciplines, inter- and trans-disciplinarity, foundations for transferable knowledge, bidirectional exchanges, and a common language. Frustrations and issues evoked were reminiscent of the tensions related to negotiating boundary crossings in the generation of a new discipline. Most cited were problems with misinterpretations in the application of neuroscientific findings to educational practice (neuromyths). A related theme indicates that direct extrapolation from one discipline to the other is inappropriate and that knowledge transferred across the boundary should be descriptive rather than prescriptive (e.g. Christodoulou & Gaab, 2009). More positively, potentials for progress were highlighted: the need for more concerted collaboration, a more skeptical approach in interpreting neuroscientific findings and their limitations in educational practice. Some literature suggests tools (boundary objects) for uniting the two disciplines: an accessible, common language and mode of communication across the boundary, ‘bridges’ through existing disciplines such as cognitive psychology, and creating research schools or shared databases on learning (e.g., Fischer, 2009). The concept of brokerage (Wenger, 1998) appears, recommending people at the boundary to facilitate the evolution of educational neuroscience, including scientists knowledgeable about educational research capable of communicating across the boundary (‘translators’) (Fischer, 2009; Christodoulou & Gaab, 2009) or existing specialists such as educational psychologists (Mason, 2009). Analyzing the educational neuroscience literature through the lens of boundary principles indicates the boundary between the two disciplines may itself be a bridging mechanism useful for the creation of a new discipline. Boundary crossings between disciplines must not be seen as obstacles, but as positive transformations that combine “different modes of thinking in the generation of new outcomes” (Dillon, 2008, p.261).

Theoretical significance:

Understanding the nature of the boundaries and resulting tensions produced by the merging of disciplines could enhance discussion about the significance of neuroscientific research as it applies to education. Continued attention to the tensions produced by this union of disciplines is a first step in clarifying the challenges of applying research findings; a second step could involve attempts to resolve these tensions. This resolution might, for example, involve the dispelling of neuromyths, the increased potential for both neuroscientists and educators to understand their own and the opposite academic culture, and the development of a common language for naming and working within the concepts important to both fields.

PAPER PRESENTATION

Involvement of inhibitory control mechanisms in overcoming intuitive interference

Ruth Stavvy, Tel Aviv University, Israel; Reuven Babai, Tel Aviv University, Israel; Stefan Elmer, University of Zurich, Switzerland; Nahed Younis, Tel Aviv University, Israel; Lutz Jancke, University of Zurich, Swaziland

Many students encounter difficulties when solving problems in science and mathematics. Research indicates that these difficulties may stem from intuitive interference with analytic reasoning. Our research aims at deepening the understanding of these difficulties and their underlying reasoning mechanisms in order to help students overcome them.

Interference or conflict between intuitive and analytic reasoning results in increment in error rate. In a previous fMRI study participants compared the perimeters of two geometrical shapes in two conditions: 1) congruent, in which correct response is in line with the intuitive reasoning (larger area–larger perimeter) and 2) incongruent, in which the correct response is counterintuitive (larger area–equal perimeter). Success rate was lower in the incongruent condition and correctly answering it specifically activated bilateral prefrontal areas known for their executive control over other brain regions. Moreover, reasoning associated with overcoming the intuitive interference was reciprocally correlated with the level of brain activation in the prefrontal region. Here we further studied the involvement of inhibitory-control-mechanisms in overcoming intuitive interference. Our findings indicate that students with strong and efficient inhibitory-control-mechanisms outperform students with non-efficient ones. In addition, a preliminary tDCS experiment suggests that stimulation of the right prefrontal cortex increases accuracy of responses in the incongruent condition. These findings further point to the importance of control mechanisms in overcoming intuitive interference. We will discuss the educational relevance of these findings.

Background and Aims

Students' difficulties in science and mathematics may stem from intuitive interference with analytic reasoning. Our research aims at deepening the understanding of these difficulties and their underlying reasoning mechanisms in order to help students overcome them. Here we focus on the comparison-of-perimeter task known to elicit intuitive incorrect responses.

In a previous fMRI study (Stavvy & Babai, 2010) participants compared the perimeters of two geometrical shapes in two conditions: 1) congruent, in which correct response is in line with the intuitive reasoning (larger area–larger perimeter) and 2) incongruent, in which the correct response is counterintuitive (larger area–equal perimeter). Success rate was lower in the incongruent condition and correctly answering it specifically activated bilateral prefrontal areas known for their executive control over other brain regions. Moreover, reasoning associated with overcoming the intuitive interference was reciprocally correlated with the level of brain activation in the prefrontal region.

We describe two studies aimed at understanding the involvement of inhibitory-control-mechanisms in overcoming the intuitive interference in the comparison-of-perimeter task.

Study 1 - Accuracy of responses of students with strong or weak inhibitory-control-mechanisms

Our aim in this study was to find out whether participants that exhibit strong inhibitory-control-mechanisms will succeed better in overcoming intuitive interference than those that exhibit weak inhibitory-control-mechanisms.

Methodology

Eighty-five ninth graders participated in the study. The strength (strong/weak) of inhibitory-control-mechanisms of each student was assessed using the digit cancellation test according to Israeli norms (Vakil et al., 2009). In this test participants were shown a pattern of digits and were required to first cross out target digit "8" and then the target digits "3" and "5". Time to completion and number of errors were measured.

We used a revised version of the computerized comparison-of-perimeter test (Babai et al., 2006). The test included 16 congruent and 16 incongruent trials. Each condition had 8 simple and 8 complex (more difficult) trials (Figure 1). In each trial two polygons were presented on a computer screen, until the participant gave a response (right is larger; left is larger; both are equal) by pressing an appropriate key.

Findings
Results are depicted in Table 1.

A 2x2x2 repeated measure ANOVA was conducted. As expected significant main effects of congruity (ppp
Significant interaction congruity x group (pp=0.002) probably due to the failure of Group2 in incongruent trials.

These findings indicate that inhibitory-control-mechanisms play an important role in overcoming intuitive interference.

Study 2 - Effect of tDCS on overcoming intuitive interference (an on going project – more data are expected by the conference time)

Neurons are known to respond to Direct Current electrical fields by altering their firing rates. Generally speaking, when the anode is located near the neurons it stimulates their activity by slightly changing the membrane potentials. In this preliminary study we explored how accuracy in the comparison-of-perimeter task is affected by tDCS (transcranial Direct Current Stimulation) to the prefrontal cortex. Will such stimulation improve participants' ability to overcome intuitive interference?

Methodology

Participants were twenty-seven (17 experimental, 10 control) right handed young adult males. All performed twice a longer version of the comparison-of-perimeter test (160 stimuli divided equally to: congruent-simple, congruent-complex, incongruent-simple, incongruent-complex). At the beginning of the testing session both groups received a 9 minute Sham treatment (1 mA applied for the first 30 seconds). Participants then responded to the test (Test1). After a pause of 30 minutes the experimental group received anodic stimulation (1 mA for 9 minutes) and the control group a Sham treatment (as before). Both groups then completed the test (Test2). Stimulation was applied in the right prefrontal region and the reference was set behind the ear. Neuropsychological test battery showed that the groups were similar in their short-term memory and visuospatial abilities.

Findings

Results are depicted in Table 2.

In the experimental group a significant improvement in accuracy from Test1 to Test2 was found in the incongruent complex condition (64% to 79%, $p=0.042$) while in the control group similar success rates were observed for this condition from Test1 to Test2 (54% to 56%). In addition, in the experimental group the mean accuracy in the incongruent condition increased from Test1 to Test2 (73% to 86%, $p=0.073$), while in the control group similar success rates were observed for this condition from Test1 to Test2 (60% to 62%).

These preliminary findings suggest that stimulating the prefrontal cortex improves participants' ability to overcome intuitive interference, possibly due to activation of inhibitory-control-mechanisms and/or other relevant cognitive functions.

Educational significance

The findings presented above point to the importance of inhibitory-control-mechanisms in students' ability to overcome intuitive interference and hence their difficulties in science and mathematics. Accordingly, our findings suggest putting more emphasis on enhancing students' executive control mechanisms in addition to supporting relevant content knowledge, as is traditionally done in schools. It should be noted that successful attempts to specifically improve executive functions have been carried out so far mainly with preschoolers (for example, Diamond et al., 2007; Rueda et al., 2005). It seems worthwhile, therefore, to attempt it with school children.

PAPER PRESENTATION

Detecting Cognitive Load Levels by Means of Brain-Computer-Interface Methodology

Gabriele Cierniak, Knowledge Media Research Center, Germany; Peter Gerjets, University of Tuebingen, Germany; Carina Walter, University Tuebingen, Germany; Martin Bogdan, University Tuebingen, Germany; Wolfgang Rosenstiel, University Tuebingen, Germany

According to Cognitive Load Theory (CLT) the type and amount of cognitive load during learning is crucial for successful learning. CLT recommends that cognitive load should not exceed working memory capacity at any time during learning. A continuous online measure of CL during learning is necessary to investigate whether learning environments meet this criterion. Antonenko et al. (2010) suggest that continuous EEG data might be used to measure instantaneous CL. In the current study we applied a Brain-Computer-Interface (BCI) methodology to test whether continuous EEG data can be used offline to classify students' CL levels during learning. The EEGs of 8 students were recorded during learning angle theorems (higher CL) and watching comic-strips (lower CL). First, it was shown that the classifiers used for BCIs and trained on the EEG data during learning theorems and watching comic-strips classified both phases on average as 73% correct. For individual students the percentage of correct classification reached 82%. Second, it was shown that binary classifiers trained on the EEG data only during learning the theorems presented in three formats (lower, medium, and higher CL), classified on average 65% between lower and medium, lower and higher, as well as medium and higher CL format. The results of this study indicate that continuous EEG data in combination with BCI methodology is a promising approach to measure learners' CL online.

Introduction

Cognitive Load Theory (CLT) proposes that the limited capacity of working memory is a crucial factor in learning. Thus, one important aspect in designing learning environments is to keep the cognitive load within the limit of learners' working memory capacity. CLT distinguishes between three CL types: intrinsic CL is caused by the content complexity, extraneous CL is caused by the design and hampers learning, whereas germane CL subsumes learners' elaboration processes that support learning. The three load types are additive and their sum should not exceed learners' working memory capacity, because learning is hampered by cognitive overload.

According to CLT it would be useful to measure instantaneous CL during learning to investigate how much CL is put on learners' working memory. Antonenko et al. (2010) suggest that instantaneous CL can be measured by continuous EEG data. Neuropsychological studies suggest that an increase in cognitive load is associated with an increase in theta band activity and a decrease in alpha band activity. We conducted the following experiment in order to test whether different levels of learners' CL can be distinguished offline by BCI methodology relying on continuous EEG data. The overall aim was to find optimal classifiers for each individual.

Experiment

Participants and Design

8 students (12-15 years old) participated in the experiment. We manipulated CL on a coarse-grained and a fine-grained level. On the coarse-grained level, students were asked to study five angle theorems (higher CL) and to watch 15 comic-strips (lower CL). On the fine-grained level, each of the five angle theorems was presented in three complexity formats (lower, medium, and higher CL). All participants studied 15 (5x3) angle theorems and 15 comic-strips to allow for within-subjects comparisons.

Procedure and Materials

The experiment consisted of four phases. In phase 1, students were asked to solve angle problems to measure students' prior knowledge (pre-test). Phase 2 consisted of three learning cycles (lower, medium, and higher CL; see Figure 1). In each cycle participants were asked to study five angle theorems and to watch five comic-strips. Each comic-strip and theorem was presented for 45 sec. After one comic-strip an angle theorem was presented. In phase 3, students applied the theorems with a German version of the Carnegie Learning's Cognitive Tutor provided by Schwonke et al. (2007). Finally, participants had to solve the first angle problems again (post-test).

FIGURE 1

Apparatus

Participants' EEG data were collected during the experiment by 16 electrodes which were placed according to the Modified Combinatorial Nomenclature expanded 10-20 system. EEG data were collected at a sampling rate of 256 Hz. EEG Data Analysis

Support-Vector-Machines (SVMs) were used for classifying the filtered EEG data. EEG spectral power analyses were run to check whether a theta band increase and/or alpha band decrease between assumed CL manipulations took place.

Results

Learning Outcomes. A RM-ANOVA indicated that all participants solved significantly more angle problems in the post-test ($M = 95\%$) than in the pre-test ($M = 40\%$; $F(1,9) = 354.77$; p

Classification 1. On the coarse-grained level, it was tested how well binary SVMs distinguished between learning angle theorems and watching comic-strips. The percentage of correct classifications reached on average about 73% with a minimum of 66% and a maximum of 82%.

EEG spectral power 1. A dependent t-test on the participants' spectral power (see Figure 2) showed a trend in that most participants' theta band increased and occipitoparietal alpha band decreased from watching comic-strips to learning angle-theorems ($p = .10$), especially over the right hemisphere.

FIGURE 2

Classification 2. On the fine-grained level, it was first tested how well 3-classes SVMs distinguished between learning angle theorems presented in lower, medium, and higher CL format. The percentage of correct classification reached on average about 42%. Binary SVMs between lower and medium CL reached on average 62% (max. 71%), between lower and higher CL about 68% (max. 80%), and between medium and higher CL about 64% (max. 74%) correct classifications.

EEG spectral power 2. Individual dependent t-tests showed that most participants' upper theta band (6Hz–8Hz) power significantly increased from learning theorems presented in lower compared to medium or higher CL format.

Discussion

The study investigated whether continuous EEG data and BCI methodology can be used to distinguish between different CL levels during learning. First, the results showed that SVMs had a good percentage rate of correct offline classifications (73%) between learning (angle theorems) and non-learning (comic-strip) phases. The percentage rates of correct offline classifications between more subtle differences in CL levels (lower, medium, and higher theorem format complexity) were lower but nevertheless reached about 65% on average. Second, the results showed that theta and alpha bands were the critical EEG frequencies indicating spectral differences between the coarse-grained CL manipulations. This result is in line with neuropsychological evidence about mental workload (Klimesch, 1999) and suggests that the SVMs probably relied on cognitive load differences rather than on surface differences in stimuli characteristics. The result that the EEG band differences appeared especially over the posterior right hemisphere probably reflects the spatial demands of processing angle theorems (Gevins et al., 1997). The study suggests that the combination of continuous EEG data and BCI methodology is a promising approach to distinguish between learners' CL levels online. This methodology might be used for adaptive learning environments.

PAPER PRESENTATION

Early number competence and working memory are key for later mathematics achievement

Caroline Hornung, University of Luxembourg, Luxembourg; Martin Brunner, University of Luxembourg, Luxembourg; Christine Schiltz, University of Luxembourg, Luxembourg; Romain Martin, University of Luxembourg, Luxembourg

Early number competence is essential for children's later mathematics achievement. Previous studies have indicated that early number competence is grounded in more basic cognitive mechanisms, such as working memory and nonverbal number sense. This longitudinal study had two main objectives. First, we examined how early number competence in kindergarteners predicted mathematics achievement one year later in first grade. Second, we examined the specific role of working memory in early number competence and mathematics achievement. Latent regression models revealed that early number competence strongly predicted later mathematics achievement. Further analyses indicated that working memory explained unique variance in early number competence when nonverbal number sense, verbal comprehension, and fluid intelligence were controlled. These findings emphasize (a) the importance of early number competence for later mathematics achievement, (b) the key role of working memory

processes in basic number and mathematical processing in young children. Early screening programs designed to identify children at risk of developing later mathematical difficulties should therefore include working memory measures. Targeted early intervention programs offer the opportunity to foster these children's cognitive and early number development and thus to promote their later mathematics achievement.

Research objectives of the present study

Previous studies acknowledged that a broad range of variables may be useful to identify the cognitive underpinnings of mathematical competence and mathematical learning difficulties (Aunola, Leskinen, Lerkkanen, & Nurmi, 2004; De Smedt et al., 2009; Koponen, Aunola, Ahonen, & Nurmi, 2007; Kroesbergen, Van Luit, Van Lieshout, Van Loosbroek, & Van de Rijt, 2009). The aim of the present study was therefore to investigate a range of cognitive variables at the end of kindergarten prone to influence mathematics achievement one year later at the end of first grade. Earlier studies reported that mathematical competence grounds either in early number skills, e.g., counting skills (Jordan, Glutting, & Ramineni, 2010; Jordan, Kaplan, Locuniak, & Ramineni, 2007; Jordan, Kaplan, Oláh, & Locuniak, 2006; Jordan, Kaplan, Ramineni, & Locuniak, 2009), in more basic number-specific processes, i.e. nonverbal number sense (Butterworth, 1999, 2005; Landerl, Bevan, & Butterworth, 2004; Landerl & Kölle, 2009), or in domain-general processes, i.e. working memory (Raghubar et al., 2009, for a review). The contribution of these different underlying processes has been studied either separately or concurrently and consequently yielded inconsistent results. For example, Jordan et al. (2009) found that early number competence was a better predictor for later mathematics achievement than working memory. Likewise, Halberda and Feigenson (2008) found that nonverbal number sense related significantly to later mathematics achievement after accounting for domain-general capacities (also see Fuchs et al., 2010). And Kroesbergen et al. (2009) found that working memory (domain-general processes) and nonverbal number sense (domain-specific processes) predicted both incremental parts of variance in early number competence.

We therefore examined the contribution of domain-general and domain-specific processes to developing early number competence and to later mathematics achievement. In line with Kroesbergen et al. (2009; No&il, 2009) we defined early number competence as a cultural acquisition (cf. biological secondary abilities, Geary, 1994, 2000) dependent on education and numerous cognitive processes that may be partly domain-general and partly domain-specific (verbal, numerical and visuo-spatial). For example, early number competence includes verbal counting skill, which requires children to recite the number word sequence in the correct order. This root counting skill implicates multiple processes: aspects of language production, knowledge of the sequence of number words and working memory to keep track of the counting process (stay on task and remember which number word comes next). From this rationale, basic cognitive abilities such as working memory, nonverbal number sense and verbal ability are likely to underlie early number competence (cf. Kroesbergen et al., 2009). Thus, in this study, early number competence, nonverbal number sense, working memory and verbal ability were conceived from a hierarchical perspective. While working memory, nonverbal number sense and verbal ability refer to more basic cognitive abilities; early number competence refers to a complex cognitive ability that grounds in basic cognitive abilities. Rather than simultaneously studying the prediction of early number competence, working memory, nonverbal number sense and verbal ability on mathematics achievement, the study is divided into two sections. The first section investigated the role of kindergarteners' early number competence on mathematics achievement. In line with Jordan and colleagues, early number competence may be determinant for later mathematics achievement (Aunola et al., 2004; Jordan et al., 2006; Jordan et al., 2009; Krajewski & Schneider, 2009). The second section investigated the cognitive underpinnings of kindergarteners' early number competence. To this end latent variable analyses examined how working memory, nonverbal number sense, verbal ability and additionally fluid intelligence (as control variable) accounted for early number competence in kindergarten.

Method

Our longitudinal study involved two measurement points: the first when participants were in the third and final year of preprimary education (i.e., kindergarten) and the second 11 months later, when they were in first grade. All participating children were taught the same first grade mathematics curriculum for 8 months. Our analyses are based on data of all 165 children who provided data for the measures at the end of kindergarten. Written parental consent was obtained for all participating children. The assessments were all conducted in kindergartens and primary schools in Luxembourg.

In kindergarten, we administered verbal counting, dot counting, and Arabic number comparison tasks to measure early number competence. WM was assessed by four verbal (e.g., digit span, backward color span) and two visuo-spatial span tasks, each beginning at a list length of two stimuli. Nonverbal number sense was assessed by two numerosity comparison tasks: a dot comparison task and a stick comparison task. In both tasks, children pressed either a pink (left) or a blue (right) button to identify the side of the screen with the larger numerosity. The first 10 test sets of the verbal comprehension test of the British Picture Vocabulary Scale (Dunn, Dunn, Whetton, & Burley,

1997) were translated into Luxembourgish and administered to evaluate children's receptive vocabulary. We measured fluid intelligence using a widely applied abstract reasoning ability task, Raven's Coloured Progressive Matrices (Raven, Raven, & Court, 1998). In first grade, we assessed three core aspects of children's mathematics achievement: arithmetic, visuo-spatial mathematical abilities, and number line estimation. For statistical analysis we conducted structural equation modeling with Mplus 5.2 (Muthén & Muthén, 1998–2007). The full information maximum likelihood (fiml) method was used to handle missing data in all analyses (cf. Schafer & Graham, 2002) due to longitudinal data.

Results and practical implications

Overall, the study highlights 2 key findings. First, early number competence is a crucial predictor for mathematics achievement as assessed at the end of first grade. Second, working memory representing domain-general abilities explains incremental variance in early number competence after controlling for basic number-specific and language abilities. Thus, kindergarteners' working memory abilities partly explain the strong relationship between kindergarteners' early number competence and their first-grade mathematics skills. This finding emphasizes the role of working memory in learning mathematics at an early stage in development and aligns with previous research underscoring the role of working memory in children's cognitive and academic development (Cowan & Alloway, 2009, Raghubar et al., 2009). These results have practical implications for early screening and intervention programs. In particular, identifying whether early number competence is grounded in domain-general processes (i.e., WM) or in domain-specific processes (i.e., nonverbal number sense) would improve the comprehension of the underpinnings' of early number development and eventual early number difficulties. This may consequently advance early screening and intervention practices in mathematics.

PAPER PRESENTATION

Doctoral examining for sustainable research capacity building – examiner threshold crossing.

Assessment methods, Higher education, Research based learning

Gina Wisker, University of Brighton, United Kingdom

In discussions of what makes a 'Good enough PhD' (Wisker 2010), a major area to be explored further is that of the practices of and standards sought by doctoral examiners. Internationally, increasing numbers of students seek doctoral qualifications (EdD, DBA, Prof Doc, PhD) in a wide variety of disciplines, or interdisciplines. Examiners consider work produced for doctorates in varied contexts whether dealing with the text alone (Australia) or the text and the viva (Europe, UK, America). It is timely to revisit early work (Kiley and Mullins 2002), build new work on doctoral examining and to ask some further hard questions about processes, behaviours, standards and quality. Current research reported here uses conceptual threshold crossing theory (Wisker, Kiley, Robinson, Aiston 2006) to consider in what ways and where examiners' examining processes engage with, identify and discover in practice indicators of the achievement of qualities expected in a marginal and in a successful doctorate. Interviews of doctoral examiners in a variety of international contexts reveal their examining processes, awareness of evidence of conceptual threshold crossing and evidence which they recognise constitutes sufficient quality to merit a doctorate.

Aims and background

In discussions of what makes a 'Good enough PhD' (Wisker 2010), a major area to be explored further is that of the practices of and standards sought by doctoral examiners. Internationally, increasing numbers of students seek doctoral qualifications (EdD, DBA, Prof Doc, PhD) in a wide variety of disciplines, or interdisciplines. Examiners consider work produced for doctorates in varied contexts whether dealing with the text alone (Australia) or the text and the viva (Europe, UK, America). It is timely to revisit early work, build new work on doctoral examining and to ask some further hard questions about processes, behaviours, standards and quality.

Methodology and methods

Current research reported here uses conceptual threshold crossing theory (Wisker, Kiley, Robinson, Aiston 2006) to consider in what ways and where examiners' examining processes engage with, identify and discover in practice indicators of the achievement of qualities expected in a successful doctorate. Our work in this area arises from two recent and ongoing projects, one UK based, one international. The UK, NTFS (National Teaching fellowship) project 'Doctoral learning journeys' (DLJ) 2007-2010, builds on and accompanies 13 years of the 'parallel project' itself partly funded by an individual NTFS. The most recent focus of both projects is a scrutiny of examiners' processes, definitions and recognition of achieved outcomes and standards in the doctorate which are indicators of success and which lead examiners to recommend a pass, or a pass with modifications. The DLJ began in 2007 with a large scale survey of UK PhD students (350), tracks learning journeys of 20 doctoral students, 20 supervisors and latterly

examiners (11), using narrative inquiry and interviews. The parallel project 1998- 2010- uses inventory data on doctoral students' learning outcomes and behaviours (@300 students) interviews with students and supervisors, and latterly interviews with examiners. Previous work on doctoral examining (Kiley, 2009; Kiley & Mullins, 2004; Mullins & Kiley, 2002, Holbrook et al 2004, c b) indicates that examiners identify a passable thesis and work which makes a recognisable contribution in terms of certain characteristics, early on in their examining processes. (Kiley M., Wisker, G., 2009, Kiley M., Wisker G., 2010) indicate that doctoral students and their supervisors are aware of moments of conceptual threshold crossing involving transformed ways of understanding, interpreting, viewing and articulating 'something'. Without such awareness it is argued, students seem unable to make a contribution to knowledge sufficient to progress at the level required for research and doctoral achievement. Mullins & Kiley, (2002) reported that a 'good' thesis demonstrates:

Critical analysis & argument	Confidence & a rigorous, self-critical approach
A contribution to knowledge	Originality, creativity & a degree of risk taking
Comprehensiveness & scholarly approach	Sound presentation & structure
	Sound methodology

In our recent interviews we asked the following questions of thesis examiners:

How do examiners recognise and comment on doctoral level achievement?	How do they discuss theses considered marginal?	What are the characteristics of marginal theses at examination?
		What are the characteristics of doctoral level achievement and conceptual threshold crossing at examination?

Findings

Our recent work reveals in practice the notion of 'examiner thresholds', threshold crossing moments for examiners triggered by the quality of the thesis when they recognise achievement and expression worthy of a doctorate. We have also identified examiners' perceptions of the characteristics of the marginal or the 'good enough' doctorate, and characteristics of the doctorate which indicates work of a higher than marginal, sometimes stunning quality. Examiners reported that they considered a 'good' thesis to have:

Sound design, methodology in action	Good qualities and cohesion throughout plus that extra 'newness' and 'flourish' which goes beyond the thesis
Engagement with the literature in dialogue	Real sense of mastery and adding something new
'The magic ingredient' 'I'm looking for somebody who really, really knows this subject so well that they're able to step beyond the subject and go somewhere new with it.they get to the margins of the theory and they're challenging' While a marginal thesis was described as:	
Too complex without order or focus	'too many beads'
Too mechanistic	'It's not illuminating, I want to see lights come on something that's moving on from that, the exception is where I see illuminated thinking coming through in the sections.'

Educational significance

Our work with doctoral examiners reveals their examining processes, awareness of evidence of conceptual threshold crossing and evidence which they recognise constitutes sufficient quality to merit a doctorate.

PAPER PRESENTATION

LINKING STUDENTS' PHD EXPERIENCE TO THEIR UNDERSTANDING OF THE THESIS

Maria Cerrato Lara, Ramon Llull University (Barcelona), Spain; Montserrat Castello, Universitat Ramon Llull, Spain

All PhD students have to face the writing of the thesis. The literature remarks it as a complex self-regulated learning task, but what do the protagonists think about it? Research on students' attitude to writing a thesis shows that action-control belief variables (academic ability, belief in luck, and knowledge orientation) are seen as having both direct and indirect effects on students' attitude to writing a thesis. We also think that students' subjective well-being in relation to their process, their learning context and of course outside the PhD can also play an important role on how students experience the writing of the thesis. With this purpose, a sample of 631 PhD students from Spain completed the PhD experience questionnaire that includes items from the MED NORD questionnaire (Lonka et al., 2008) that were modified to fit the PhD context in Pyhälä, Stubb & Lonka (2009) and items from The Writing Process Questionnaire (Lonka, 1996, 2003, 2007). After an analysis of factors and reliability of the instrument, a correlation analysis of factors and 2nd order factors was made with interesting results and also in relation to gender, age and discipline. A qualitative analysis was also made with 300 of the participants to complement the results by analyzing seven of the open-ended questions of the questionnaire that we considered could give us relevant information for our purpose.

Students' representations of academic tasks are crucial to understand how they develop them (Pozo, Scheuer, Mateos & Péerez Echeverría, 2006). We guess this is not an exception for PhD students with their thesis and this is why in this research we are interested in investigating how students understand the thesis. The literature reviewed concerned about the doctoral experience, that is, how students perceive this process, focuses on well-being aspects, learning environment aspects and writing aspects. In relation to the first group, Beauchamp, Jazvac-Martek & McAlpine (2009), for example, study the tensions inherent in the doctoral experience. In relation to the second group, we found a study of Rachel (2009), for example, that focuses on PhD students' perceptions of the community learning experience. In relation to the third group, Sachs (2002), for example, makes research on students' attitude to writing a thesis. As a fact it has to be highlighted that literature in the field of Doctoral studies is not very extensive.

We take into consideration these three variables –well-being, learning environment and writing perceptions- with the hypothesis they contribute in the understanding PhD students have of the thesis. In order to test it, 206 PhD students developing their doctoral studies in Spain were asked to answer, respecting their anonymity, the PhD experience questionnaire (Lonka, 1996; Lonka, 2010 in press) that combines 8 open-ended questions, 49 Likert type statements and 18 background questions. Before passing the instrument we proceeded to its validation in the Spanish population with a sample of 67 PhD students and now this work has been sent to be published (the authors and Martínez-Fernández, sent).

For this study we analyzed one of the eight open-ended questions (the one related to students' understanding of the thesis) and 39 of the 49 Likert type statements (8 related to well-being variables –anxiety, exhaustion and lack of interest specifically-, 15 related to learning environment variables –atmosphere, feedback and workload specifically- and 16 related to writing variables –perfectionism, knowledge creation, productivity and general negative self-perceptions as writers specifically).

In relation to students' understanding of the thesis (the open ended question), we applied a qualitative methodology analysis using the Atlas-ti software and afterwards we calculated the percentages. Results in this part of the research show us that the thesis is perceived as an opportunity to deep on a topic of interest (29%), a contribution to the society (13%), an emotional experience (14%), an opportunity to learn (12%), a way to transfer knowledge to the practice (12%), a personal challenge (8%), a way to get part in the academic community (7%) and others (5%).

Regarding the Likert type statements, the SPSS software was used for the data analysis and some correlation analysis were applied. Regarding to this, we have some results that the literature corroborates: anxiety is significant and negatively correlated with production ($r = -.594$; pBoice & Johnson (1984) in their research observed that productive writers experience little anxiety and Onwuegbuzie (1999) in his research concluded that students with the lowest perceived scholastic competence and perceived creativity tended to have the highest anxiety about writing.

Linking students' PhD experience to their understanding of the thesis, an interesting result to remark is that students with perceptions of the thesis in which the learning aspect is especially highlighted (41%) perceive less workload in their doctoral studies in comparison the rest of the sample. In the conference we will show you results in detail.

We think this investigation can contribute to rethink and reflect on the quality of doctoral programs. We guess students' voice is a powerful tool that can give us clues for this and very often we don't pay attention to it. From the point of view of the supervision, if tutors have information about how their students experience PhD studies, they

may be able to understand better how their students carry out their thesis and can then offer a more adjusted help in this process taking into account that writing a thesis can be characterized as the ultimate self-regulated learning task (Sachs, 2002) and it is then important students are to be guided successfully through this process.

PAPER PRESENTATION

The many faces of deep approach – what are we really measuring?

Juha Nieminen, University of Helsinki, Finland; Annamari Heikkilä, University of Helsinki, Finland; Kirsti Lonka, University of Helsinki, Finland

Investigating deep and surface approaches to learning by self-report instruments entails difficult choices regarding the context the respondents are expected to keep in mind while rating questionnaire items. It may be useful to try to distinguish between what students believe to be important and what they try to do when studying in a particular context. Finnish and Swedish students (N=1839) rated statements on a number of study practices typically associated with either a deep or a surface approach to learning. Three scales reflecting students' views on the importance of certain study practices, and three matching scales measuring their application, were created. For deep approach, application scales showed lower means and larger standard deviations than importance scales. Critical evaluation of knowledge and aiming to understand content appeared as two differing, related aspects of deep approach. Aiming to understand was consistently linked with study success. Medical students reported lower levels of critical evaluation than students from other domains. Measuring simultaneously the importance and application of approaches appears a promising strategy for investigating student learning.

Theoretical background

An extensive literature on student approaches to learning (J. B. Biggs, 1993; N. J. Entwistle & McCune, 2004; Richardson, 2000; Watkins, 2001) shows that university students vary in what they see as important in learning and in how they perform learning tasks. The distinction between deep and surface approaches to learning has proven to be a fruitful conceptualization of student learning, inspiring an extensive tradition of empirical research.

The multilayered nature of the phenomena poses a challenge to a researcher trying to decide which aspects should be measured and which distinctions can be empirically studied. When measuring approaches to learning by self-report instruments, it is often difficult to know to what extent students answered based on what they believe to be beneficial in learning and to what extent based on their context-specific approaches.

Aims

We set out to measure simultaneously a) what kinds of learning processes students believed to be useful in studying and b) to what extent they would report adopting those strategies while preparing for an examination. We were interested in whether the measurement of approaches to learning might be improved by specifying a context of application to keep in mind when rating questionnaire items.

Methods

Three groups of students participated in this study. The first group consisted of 865 Finnish students from faculties of arts (n=360) agriculture (n=302), and law (n=203). The second group consisted of 626 medical students from three Finnish medical schools, and the third group of 348 Swedish medical students.

Based on previous inventories such as the Approaches to Study Inventory ASI and the Inventory of Learning Styles ILS, we formulated statements describing a variety of study practices. The items were expected to reflect two types of approaches to studying, a deep approach (e.g., "It is important to try to relate details to a bigger whole"), and a surface approach (e.g., "It is important to memorize new definitions and scientific concepts as literally as possible"). After each statement, students were to answer to the statement "I do this when studying for an examination". All statements were rated using a Likert-scale ranging from 1 (totally disagree) to 6 (totally agree). Study success was measured as self-reported grades and, for the Finnish multi-faculty students also as actual GPA's obtained from university archives.

Results

To investigate the structure of the scales, maximum-likelihood factor analyses with Varimax rotation were performed. Confirmatory factor analyses are currently underway and preliminary results support the factor structure obtained by maximum likelihood factor analyses. Based on the results of the factor analyses, three composite scales were created to measure experienced importance: Importance of Critical Evaluation, Importance of Understanding, and Importance

of Surface Approach. Further, for each of the three importance-focused scales, a corresponding application-focused scale was constructed using the follow-up items ("I do so when reading for an examination"). Altogether, we created three pairs of scales: Importance of Critical Evaluation and Application of Critical Evaluation; Importance of Understanding and Application of Understanding; Importance of Surface Approach and Application of Surface Approach. Reliabilities ranged from acceptable to good for most of the scales. Reliabilities were slightly higher for the scales measuring application than for the scales measuring importance, except for the Critical Evaluation scales in the Swedish medical data.

*The means of Importance of Understanding were extremely high, over 5.0 in all student groups, indicating that all students valued understanding highly. This was also the case for Importance of Critical Evaluation in the multi-faculty group. In the medical student groups the means of Importance of Critical Evaluation were also high, yet significantly lower than they were in the multi-faculty group. The means of the surface approach scales were slightly above the mid-point of the rating scale. The means of importance scales and application scales differed significantly from each other in all student groups.

In the Finnish multi-faculty sample the pattern of associations between approaches to learning and study success was very clear, confirming earlier results: all the scales measuring aspects of deep approach were positively linked with grades. This was true also for grades received for the four-year period after students had filled in the questionnaire and even for grades received on Master's theses. In the medical data, both the understanding aspect of deep approach and surface approach showed a small significant correlation with grades. Results regarding the link between surface approach and grades were rather weak.

Conclusions

The results indicate that university students may respond extremely positively to items measuring the importance of practices related to deep approach, but give considerably lower ratings to scales measuring their application in specific contexts of studying. The results further indicate that inquiring about students' practices in a specified context of studying may improve the reliability of scales. In addition, applied scales may capture more variance than scales of more general nature.

The present study indicates that what students' believe to be important in university studies and what they do when preparing for examinations differ from each other at least when measured simultaneously, and that it is possible to empirically distinguish these aspects of approaches to learning. Furthermore, critical evaluation of knowledge and aiming for understanding appear to be adopted to varying degrees in differing academic domains. Seeking to understand while studying for an examination seems to be the variable most consistently related to study success, even for grades received on Master's theses.

PAPER PRESENTATION

Development Of Teacher Candidates' Professional Competencies During a Practical Internship

Alexander Groeschner, Technische University Munchen, Germany; Tina Seidel, Technische Universität München, Germany; Cordula Schmitt, Institute of Psychology, University of Jena, Germany

Opportunities of learning to teach (such as internships) are considered as valuable for developing professional competencies in pre-service teacher education (Zanting, Verloop, & Vermunt, 2001). However, research mainly concentrates on interventions such as student mentoring. So far, knowledge about teacher candidates' development of professional competencies during such teaching practice is limited. The study presents findings from a research project monitoring the development of professional competencies in a semester of practical internship. Teacher competencies were assessed by means of a newly developed instrument, including four scales of teaching skills (Cronbach's Alpha .87), evaluation (.83), classroom management (.86), self-regulation (.76). In a pre- and post-test 239 teacher candidates were investigated. Furthermore, learning experiences during the practical internship were assessed by means of the quality of mentoring at school (.86) and quality of mentoring at university (.89). In addition, both aspects were investigated by means of teacher candidates' perceptions of effective methods (7 items) and instruction (3 items) in class. Findings show a significant development of teacher candidates' professional competencies during the internship in all areas (Cohen's $d = .31$ to $d = 1.05$). Furthermore, the scientific guidance through an accompanying university course is systematically related to the development of teacher candidates during their teaching practice ($F(3;134) = 1.85$, $pF(3;134) = 1.06$, n.s.). Although, observed mentors' teaching is related to teacher candidates' own teaching ($r = .31$ to $.55$). The study contributes to identifying factors that can help to explain effective internship-terms in teacher education.

Theoretical background and research question

The evaluation of development and outcomes of initial teacher education has been increasingly becoming important for the improvement of teacher education (Darling-Hammond, 2006). With regard to developing practical competencies of teacher candidates internships are considered as being valuable learning opportunities in both students' and teachers' perspective (Zanting, Verloop, & Vermunt, 2001; Orland, 2001). Especially long-term internships are considered as fruitful places of learning because they also provide sustainable experiences of mentoring (Hobson et al., 2009). According to the definition of competence as conglomerate including skills, knowledge, and beliefs (Weinert, 2001), internships have the potential to support the transition process from student to teacher as well as to developing professional competencies (Velez-Rendon, 2006). Educational research on the acquisition of competencies in teacher education still lacks instruments and studies taking into account the sophisticated role teaching practice has for teacher candidates (Graham, 2005).

Therefore, the study presented here concentrates on three research aspects: (1) developing an instrument (based on self-reports) adequate for measuring practical experiences in internship-terms in pre-service teacher education, (2) investigating the development of teacher candidates' professional competencies during a practical internship-term, and (3) investigating the quality of mentoring at the school and university during the internship. The four-month internship term combines elements of practical experiences at schools and course work at university. The university courses concentrate on planning and performing a lesson as well as on reflecting upon the educational content of effective instruction.

Methodology

We initiated a research project focusing on the development of professional competencies in a long-term internship. At two measuring points (before the internship-term, after the internship-term) 239 pre-service teachers have been investigated at a German university. The sample consists of 56.1 % female and 43.9% male pre-service teachers. Overall, the mean age of the participants was 21.55 (SD=1.46) and in average they were attending their 5th semester of study program (SD=.45). To assess the competencies an instrument was developed with four seven-point Likert-type scales (ranging from 1= "not at all competent" to 7="full competent") in the areas teaching skills (11 items, (Cronbach's Alpha .87), evaluation (7 items, .83), classroom management (9 items, .86) and self-regulation (6 items, .76) (Grßschner, 2009). Furthermore, learning experiences during the practical internship were assessed by means of the quality of mentoring at school (12 items, .86) and the quality of mentoring at university (7 items, .89). Both mentoring aspects were additionally investigated by means of teacher candidates' perceptions of teaching methods used by mentors and in own lessons (7 single items, e.g. group-work) as well as effective instruction taught in university courses and observed in mentors' lessons and realized in own lessons (3 single items, e.g. goal clarity).

Findings

Pre-service teachers' professional development increased significantly ($p = 1.05$), followed by self-regulation (Cohen's $d = .57$), evaluation (Cohen's $d = .37$) and classroom management (Cohen's $d = .31$). Multivariate analyses show that the scientific guidance through an accompanying university course – with regard to pedagogical content knowledge (PCK) – is systematically related to the development of teacher candidates during their teaching practice ($F(3;134) = 1.85$, $pF(3;134) = 1.06$, n.s.). With regard to the perceptions of teaching methods and effective instruction we found positive interrelations between what teacher candidates observed in mentors' classes and what they tried to realize in their own teaching attempts (from $r = .31$ to $r = .55$; $pM = 3.65$, $SD = .88$; range from 1='not performed' to 5= 'performed') and student discussions ($M = 3.03$; $SD = 1.01$). With regard to aspects of effective instruction they particularly referred to goal clarity ($M = 4.30$, $SD = .65$) during their practical internship.

Discussion

The findings of the presented study show that internship-terms are valuable teaching-learning environments for developing teacher candidates' professional competencies. With regard to mentoring accompanying university courses seem to have the potential to scaffolding practical experiences during the internship-term. The fact, that there was no significant effect of mentoring at schools on the development of professional competencies could be traced back to the overall highly positive values pre-service teachers reported for the quality of mentors' guidance. Taking teacher candidates' perceptions into account our findings emphasize on the importance of the qualitative aspects of mentors' teaching practice (e.g. using different teaching methods) for the development of pre-service teachers' professional competencies. Scientific and educational relevanceThe study contributes to teacher research with regard to identifying factors that can help to explain effective internship-terms and the organization of practical experiences. It highlights the importance of institutional mentoring in school and university.

PAPER PRESENTATION

Cooperative and competitive learning in biology education

Sarah Sennebogen, Ludwig-Maximilians-University, Germany; Birgit Neuhaus, Ludwig-Maximilians-University, Munich, Germany

Cooperative learning is used in schools by many practitioners and has been evaluated in the past decades by many researchers comparing cooperative learning with competitive learning. National Education Standards claiming to enhance not only the students' competences, e.g. in inquiry acquisition became effective in Germany in 2005. Therefore, new teaching methods, like the Egg-Race, are necessary. Egg-Races combine cooperative and competitive learning environments because students work in cooperative small groups which are competing against other groups. The presented study evaluates the small group competitions' influence on achievement, expert interest, situational interest and perceived interaction within the group in the teaching unit 'forest' in a pre-post-test-design. 111 6th graders from secondary modern school took part in the study. Results show that the cooperative competition can enhance the achievement, expert interest and situational interest. But it also reveals a negative influence on perceived interaction within the group. Nevertheless, subsequent studies should examine the validity of the results for other learning contents and the influence of small group competition on social-psychological variables.

Discussion and Forecast

The results demonstrate that cooperative competition can enhance achievement, compared to pure cooperative learning environments. Therefore, the results of Julian and Perry (1967), who evaluated psychology students, can be verified for biology education. The present study also proved that cooperative competition has a positive influence on expert interest in biology education. Due to the possibility of winning a prize, the students in the competitive treatment also showed higher situational interest. Moreover, the study proved that students in the non-competitive treatment were more satisfied with the perceived interaction within the group. This again supports the results of Julian and Perry (1967), who argue that the tone in pure cooperative learning environments is warmer. Connected with a context-oriented and problem-oriented approach, Egg Races are able to complement biology education in a reasonable way. Future studies should survey if the results are valid for other learning contents and older students. The focus should be on the perceived interaction in the small group. Results of these studies and further Egg Races with biological content will be presented at the EARLI 2011.

PAPER PRESENTATION

Development and validation of a self-report instrument for exploring team work in schools

Taiga Brahm, University of St. Gallen, Switzerland; Annette Bauer-Klebl, HSG, Switzerland; Saskia Raatz, University of St. Gallen, Switzerland

Cooperative learning is a popular method for classroom teaching since it makes it possible to accommodate for individual differences as well as to achieve various educational goals (academic as well as social). Additionally, it aligns with the socio-constructivist notion of learning (Antil et al., 1998). However, when looking at everyday practice in classrooms, cooperative learning seems to not always be able to hold its promises. One reason for this might be that certain framing conditions are neglected in classroom practice which would be necessary for the effectiveness of cooperative learning (Abrami & Chambers, 1996). Due to the complexity of teamwork, it is a challenge for teachers to identify the reasons why teamwork in the classroom does not lead to the results expected. This study aims at developing and validating a self-report instrument for assessing team work at schools and for providing teachers with hints on how to improve teamwork in their classrooms. The instrument will be validated with about 400 students of at least 4 different schools. The scales are theoretically founded and cover relevant aspects of teamwork at school. All instruments were either originally developed for usage in schools or adapted to the school context. Even though further validation is necessary, the first results are already quite promising. In sum, this study provides a valuable instrument for both practitioners and researchers.

Cooperative learning is a popular method for classroom teaching since it allows for the accommodation of individual differences as well as for achieving various educational goals (both academic and social), and it is in tune with the socio-constructivist notion of learning (Antil et al., 1998). There is a vast amount of research on cooperative learning and it has been called "one of the greatest success stories in the history of educational research" (Slavin, 1996, 43). The effects of cooperative learning on student achievement were studied in many different settings, in both laboratory and field studies. However, looking at the common practices in classrooms, cooperative learning seems to not always be able to come up to the often high expectations. One reason for this might be that some of the framing conditions determining the effectiveness of cooperative learning are not taken into account in classroom practice. For instance, it is frequently neglected that the learning task needs to be suitable for cooperative learning (Abrami & Chambers, 1996). Since teamwork is very complex, it is a challenge for teachers to identify the reasons why teamwork in the classroom does not lead to the expected results. Theoretical and empirical contributions to teamwork show that there are various determinants of good collaboration. These determinants can be systematized according to so-called input-process-output models (e.g. Ilgen et al., 2005; Van den Bossche et al., 2006). Such models take into account that various input factors, i.e. personal prerequisites (motivation, team competence, self-efficacy) and task characteristics (complexity of the task, team size), influence the processes of team work. These processes include task-related as well as social aspects, such as communication among team members, reflection processes, trust and cohesion. These processes mediate the influence of the input factors on the results of team work. Yet, according to the authors' knowledge, there is no comprehensive instrument to evaluate teamwork in the classroom. Most instruments available are only validated for work contexts but not for learning contexts, especially not at schools. Instruments suitable for schools usually only cover some few aspects of teamwork.

The aim of this proposal is to report on the development and validation of a self-report instrument for assessing team work at schools and for providing teachers with hints on how to improve teamwork in their classrooms. Since the instrument is empirically validated, it can also be used for research purposes.

The methodology of the study is based on a quantitative approach. In a first step, a number of already existing instruments was selected. The selection criteria for these instruments were a) that they had already been empirically validated in other studies and b) that they were suitable for the school context, especially for the target group of 15-18 year old learners. The instruments were then recombined resulting in three questionnaires (one for the input, one

for the process, and one for the output of the teamwork). Up to now, the questionnaires have been employed at 4 different schools with 10 classes. Up to now, about 100 pupils took part in the study leading to an initial validation. Over the next 6 months, the questionnaires will be used with about 400 learners so that the results of this comprehensive validation can be reported at the conference. The data is gathered in real group work settings at different schools such as grammar schools, high schools and colleges for vocational education. The learners are between 15 and 18 years old so that complex group task are possible. To analyze the data, reliability analyses, factor analyses, and structural equation modeling were used.

The findings of the study include a general confirmation of the proposed instrument including input, process, and output constructs. Input factors are assessed by learning and performance motivation (SELLMO, Spinath et al., 2002), self-efficacy (Jerusalem & Satow, 1999), and the attitude towards teamwork (Freeman, 1996). Cronbach's Alpha of these scales ranges between .648 and .879. To evaluate the collaboration process, task cohesion (Sargent & Sue-Chan, 2001), group potency (Rohn, 2006; Campion et al., 1993) trust (Jarvenpaa & Leidner, 1999), team reflexivity (Schippers et al., 2007), task interdependence (Van der Vegt et al., 1999), participation (in analogy to Rohn, 2006; Campion, Medsker & Higgs, 1993), task and relationship conflicts (Jehn, 2005; Saavedra, 1993; Jehn & Mannix, 2001) were assessed, providing reliabilities between .740 and .852. The outcome of the team process is surveyed by task effectiveness (Saavedra, 1993; Rohn, 2006) and by satisfaction with the results (Nelson & Coopridge, 1996; Earley & Mosakowski, 2000) with Cronbach's Alpha between .644 and .907. In order to receive objective performance data and thus, to avoid common-method bias, the performance of the teams is also assessed with a grade. Both, factor analyses as well as structural equation modeling yield a confirmation of the factor structure.

All in all, this study provides a useful instrument for both practitioners and researchers to comprehensively evaluate teamwork at schools. The scales are theoretically founded in the input-process-output model covering relevant aspects of teamwork at school. All instruments were either originally developed for usage in schools or have been adapted to the school context. While the instruments will be further validated with more students within the next six month, the first results are already quite promising. They show that the basic structure of the questionnaires is valid and that the instruments are reliable.

In addition to providing instruments for research and practice, the study also contributes to theory building by taking the research on teams from other organizational contexts into account and relating it to teaching and learning in schools. This combination of two research strands leads to a comprehensive understanding of teamwork in schools and can further enhance our understanding of cooperative learning.

PAPER PRESENTATION

Motivation regulation in groups: Theoretical considerations about the learning partner's motivation

Cornelia Schoor, TU Dresden, Germany; Susanne Narciss, Technische Universität Dresden, Germany; Hermann Koerndle, TU Dresden, Germany

Regulating learning in groups is an emergent topic in educational research. Like individuals in self-regulated learning, groups have to handle cognitive, metacognitive, and motivational tasks during their learning process. Therefore, motivation regulation is one aspect of shared regulation in groups. In this paper, we focus on one particular aspect of motivation regulation in groups, namely on the role the motivation of the learning partner plays. First evidence stem from research on providing a collaborative learning group with feedback about their members' motivation. Feeding back motivational parameters of the group members seems to have a positive effect on motivation. On the other hand, research on motivation gains and losses in groups shows positive and negative effects the motivation of the learning partner has for one's own effort. As so far a theoretical model integrating these results is missing, we suggest applying a regulation model stemming from system theory and feedback research to the role the learning partner plays in group motivation regulation. The interactive two-feedback-loop (ITFL) model for instructional feedback by Narciss (2008) assumes an internal feedback loop of the learner and an additional external feedback loop of a teacher or instructional medium. We translate this model into group motivation regulation by assuming the external feedback loop to be the motivational feedback from the learning partner. This model is not only able to explain the mentioned results but also constitutes a suitable basis for specific research questions and for a more elaborated model on shared group regulation.

Regulating learning in groups is an emergent topic in educational research (c.f. Järvelä, Järvenoja, & Veermans, 2008; Vauras, Liskala, Kajamies, Kinnunen, & Lehtinen, 2003). Like individuals in self-regulated learning, groups have to

handle cognitive, metacognitive, and motivational tasks during their learning process. Therefore, motivation regulation is one aspect of shared regulation in groups.

In this paper, we focus on one particular aspect of motivation regulation in groups, namely on the role the motivation of the learning partner plays. So far, there are some empirical results, which we briefly review, but no theoretical framework. Therefore, we suggest applying a regulation model from feedback research to this topic. In collaborative learning, the learning partner's motivation can either be explicitly stated or it can be deduced from the partner's behavior.

First evidence on the role the learning partners plays in group motivation regulation stem from research on providing a collaborative learning group explicitly with feedback about their members' motivation (e.g. Martens, 2009; Zumbach, Reimann, & Koch, 2006). Martens (2009) used the „Quality of Working in Groups Instrument" (QWIGI) by Boekaerts and Minnaert (2003) to support students in statistics courses. Half of the participants filled in the QWIGI (covering autonomy, competence, and social relatedness) after every course session while a control group filled in a questionnaire about the course design. Both groups were fed back their own ratings as well as the mean ratings of their small group, and were encouraged to discuss this. After ten weeks, the QWIGI group showed significantly more intrinsic motivation than the control group. Zumbach et al. (2006) compared collaborative groups who either received or did not receive feedback of parameters of participation, motivation and emotion. They found positive motivational effects of feeding back these parameters.

Another line of research on the role of the partner's motivation is research on motivation gains and losses in groups where the partner's behaviour provides implicit feedback on her motivation. Kerr (1983), for example, showed that low effort of a capable partner reduced own effort in an air pumping task. On the other hand, there are results showing that participants were even more motivated (in terms of effort) when their partners exerted less effort (e.g. Liden, Wayne, Jaworski, & Bennett, 2004). So far, there has been no attempt to integrate these results into a coherent model. Therefore, we suggest applying a regulation model stemming from system theory and feedback research to the role the learning partner plays in group motivation regulation. The interactive two-feedback-loop (ITFL) model for instructional feedback by Narciss (2008, c.f. figure 1) assumes an internal feedback loop of the learner and an additional external feedback loop of a teacher or instructional medium. After, for example, having solved a task, the learner generates internal feedback which is compared to her internal reference value (e.g. her goal of task performance). Additionally, there is an external sensor which provides the external controller (e.g. the teacher or the instructional medium) with an actual value (e.g. perceived task performance) that is compared with an external reference value (e.g. the goal the teacher set). The resulting external control action (e.g. the feedback of the teacher to the learner) is fed back to the learner as additional input to the internal controller. The internal controller now compares internal feedback, internal reference value and external feedback, before she generates an internal control action (e.g. more effort on the next task)

We translate this model into group motivation regulation by assuming the external feedback loop to be the motivational feedback from the group. For example, feeding back motivation of the group (Martens, 2009; Zumbach et al., 2006) is collecting motivation data by means of an external sensor, processing it in the external controller by comparing it to the other group members' motivation data (external reference value), and feeding it back to the learner in terms of a group mean value and her own value (external feedback). Also, findings on motivation gains and losses subject to the partner's motivation fit well into this model. Diverging results can be attributed to different handling of feedback by the internal controller (c.f. Butler & Winne, 1995): Under some circumstances, a lower motivation of the partner seems to increase the internal reference value, while in other cases, the internal reference value is decreased. This model provides us with concrete hypotheses and research questions for future research (e.g. the effect of motivation feedback depends on a reference value being available, learners dispose of different alternatives how to treat external motivation feedback) as well as with a suitable basis for a more elaborated model on shared group regulation.

PAPER PRESENTATION

Enhancing students' socioscientific decision making: the influence of cooperative trainings

Sabina Eggert, Georg-August-University, Germany; Rainer Watermann, Georg-August-University Goettingen, Germany; Marcus Hasselhorn, DIPF, Germany; Susanne Boegeholz, Georg-August-University Goettingen, Germany

The implementation of socioscientific issues within the science classroom has been identified among science educators and curriculum developers as one core element in order to support students becoming informed citizens. Socioscientific reasoning and decision making comprises several elements such as the ability to search and evaluate relevant information, the ability to argue and reason about possible solutions strategies or the ability to reflect on decisions processes, including inherent values and norms. Thus, evaluation and monitoring processes play an important role. In the presented study, we examined the effect of two cooperative learning settings on students' socioscientific reasoning and decision making. Group one worked in a cooperative learning environment (COOP), while group two worked in a cooperative learning environment with an additional metacognitive training (COOP META). We used a quasi-experimental pre-posttest design. Data analysis was conducted using probabilistic as well as classical test theory. Data analysis addressed two main questions: the aspect of measuring invariance as well as the differential effects of both treatment groups. Results showed that partial invariance was ensured. A repeated measures ANOVA showed main results for measurement point in time as well as treatment. However, no interaction effect could be found. Implications concerning the measurement procedure as well as optimization of both treatment group designs are discussed.

The implementation of socioscientific issues within the science classroom has been identified among science educators and curriculum developers as one core element in order to support students becoming informed citizens (cf. American Association for the Advancement of Science, 1991; KMK, 2004; National Committee on Science Standards and Assessment, 1996). Socioscientific issues represent real-world scenarios of modern science. They are usually complex in nature and do not have a clear cut solution. Instead, several possible options have to be considered in a multi-perspective way, including scientific as well as economic and social aspects (cf. Sadler, Barab & Scott, 2007; Ratcliffe & Grace, 2003; Zeidler et al., 2003). Socioscientific reasoning and decision making comprises several elements such as the ability to search and evaluate relevant information, the ability to argue and reason about possible solution strategies or the ability to reflect on decisions processes, including inherent values and norms (Eggert & Bögeholz, 2010; Gausmann et al., in press; Jimenez-Aleixandre, 2002; Kolsto, 2006; Sadler et al., 2007; Zohar & Nemet, 2002). Thus, evaluation and monitoring processes play an important role.

The aim of our study was to examine the effect of a metacognitive cooperative training on students' socioscientific reasoning and decision making competencies. On the basis of Mevarech & Kramarski's work on the effect of different metacognitive trainings on mathematical problem solving (cf. Mevarech, 1999, Kramarski, Mevarech & Arami et al., 2002, we designed to training groups.

In group one (COOP), students worked in a cooperative learning setting that was characterized by the five principles of cooperative learning (cf. Slavin, 1982). In group two, students worked in the same cooperative learning setting, but got an additional metacognitive training (COOP META). The metacognitive training was developed on the basis of four metacognitive question types proposed by Mevarech & Kramarski. We used a quasi-experimental pre-posttest design

to analyse the influence of these two cooperative learning settings on students' socioscientific reasoning and decision making. Specifically, we focused on students' abilities to compare different solutions strategies with respect to socioscientific issues and to reach an informed decision.

The participants in this study were 258 seventh grade students from German grammar schools. Their mean age was 12.84 years; 128 female). The two treatments were implemented within the usual science course of the seventh graders. The topic of both treatments was the sustainable development of rivers and riverbanks. Both treatments were designed together with experienced science teachers, who were also experienced in teaching socioscientific reasoning and decision making. Teachers were randomly assigned to the two treatment groups. In total, 118 students took part in the COOP training and 140 students took part in the COOP-META training. Both treatments were equal with respect to time, science topics and socioscientific issues covered. While students in the COOP-META group answered the metacognitive questions, students in the COOP group worked on the science topics in more detail. Students' abilities with respect to socioscientific reasoning and decision making were measured using a pre- and posttest.

The questionnaire used was developed in several studies prior to this intervention study (cf. Eggert & Bßgeholz, 2010). The questionnaire presented three different socioscientific issues. For all three issues students had to answer open-ended questions. In total, 13 polytomous items were used to score student's answers. With respect to the pretest, WLE person separation reliability was 0.98; Cronbach's $\alpha = 0.73$. With respect to the posttest, WLE person separation reliability was 0.99; Cronbach's $\alpha = 0.86$.

Data analysis was conducted using probabilistic as well as classical test theory. Our analysis was concerned with two main questions. First, we analysed whether the questionnaire that was used in the pre- as well as in the posttest really measured the same latent construct. Second, we compared both treatment groups with respect to their performance on the socioscientific decision making questionnaire using a repeated measures ANOVA. With respect to the first question, we modeled students' performances on the pre- as well as on the posttest using the Rasch Partial Credit Model (Masters, 1982). We estimated person ability using Warm's Likelihood Estimates (WLE). To analyse the prerequisite of measurement invariance, we compared WLE estimates for the pre- and posttest using a graphical model test as well as comparing logit differences (cf. Wilson, 2005).

Results showed that some items or some itemsteps respectively exhibited differential item functioning (dif). In order to compare person abilities between the first and the second measurement time, we used item difficulties estimated at T1 to estimate item difficulties at T2. Those items that exhibited differential item functioning were estimated without parameter fixation. Thus, partial invariance of item parameters was ensured. Secondly, we used person ability estimates to conduct a repeated measures ANOVA. Results showed that both groups performed significantly better on the posttest. We found main effects for time ($F(1,256) = 17.240$, $p(1,256) = 6.136$, $p(1,256) = 1.751$, $p > .05$).

These findings have several implications. Firstly, the analysis of measurement invariance showed that some items or itemsteps respectively were disproportional easy at the second measurement point in time. One reason for this could be that teachers of both treatment groups focused on these aspects in their science classrooms to a great extent. On the contrary, items that were concerned with the evaluation of decision making processes were disproportional difficult at the second measurement in time. Consequently, one can deduce that teachers in both treatment groups did not foster these elements. Thus, one future aim is to optimize the design of the COOP-META group especially with respect to the aspect of evaluating and reflecting on decision making processes.

PAPER PRESENTATION

Self-regulation in learning: the process of information

DAVID MARTIN SANTOS MELGOZA, Universidad Autonoma Chapingo, United Kingdom

This work presents an ontological perspective on the study of academic learning. As there is a growing body of work concerned with personal epistemology, we will make two considerations regarding the process of academic learning: 1) concerning with what Richter and Schmid (2010) define as epistemic strategies, that we identify as the action of assigning epistemological status to information, and 2) the process of building knowledge, seen as a process of becoming aware of the objective quality of academic information. It is assumed that knowledge is systematized information ordered by a function of logical criteria of validity. It is sustained in formal or empirical evidence and is maintained as valid as long as no contradictory evidence is presented. If the organization, coherence and unity of the scientific knowledge taught is different from that existing in the subject's mind, what interactions should take place

between the subjective information schema and knowledge? We may tackle this inquiry assuming the relation object-of-knowledge-subject-of-knowledge where knowledge is an entity, but we may assume that the metacognitive focus could be directed to the knowledge as a process of "knowing", where, ontologically the difference emerges from the fact that knowledge taken as an entity (a noun) is taken as a finished object, but any knowledge is the same in the page of a book as in the experience of the student

This work presents an ontological perspective on the study of academic learning. As there is a growing body of work concerned with personal epistemology, we will make two considerations regarding the process of academic learning: 1) the first, associated with what Richter and Schmid (2010) define as epistemic strategies, that we identify as the action of assigning epistemological status to information, and 2) the process of building knowledge, seen as a process of becoming aware of the objective quality of academic information.

Perhaps an easy way to illustrate these considerations is with a specific teaching-learning situation I was involved in Mexico, where a task had been given to Robin, a young man who has some autistic characteristics, in order to prepare him for "normal life". Due to his echolalia (repeating back what is said to him), we were never sure of what he had taken from what we were trying to teach him. In the task, Robin had to choose the right nut for a specific bolt from a basket of mixed-up nuts of various sizes. In order to motivate him, every time he chose the correct nut for a bolt I shouted and jumped with joy, so he tried to do it well in order to make me happy. After several tries at this task, he always chose the right nut, so I called a colleague to have a go, but Robin could no longer choose the correct nut for him. After repeating the training, I realized that what Robin had learnt was to identify the answer in my face; every time he chose a nut he looked at me and saw my expression. So what he learnt, in giving the expected answer, was related to different elements of the context. The aim for Robin was not the same as the aim for me.

Now, in a school learning situation the student may not be aware of (or know) what and how to learn or why to act or what for. For a student to be able to direct behavior toward learning, it is necessary for the learner to make skills an object of knowledge, to both identify available information and understand it as an analyzable object, thus gradually becoming aware of what is required to be successful in dealing with information. Knowledge of their own skills can direct learners more precisely and clearly in constructing their own informational schemata that acquire, for them, the category of knowledge (Weinstein, et al., 1998). Even when the student is committed cognitively to a task, for example, the solution to a mathematical problem can represent, in adaptive terms, a means of reaching multiple ends (Manasero y Vazquez, 1995; Entwistle, et al., 1989; Wigfield & Eccles, 1992; Weiner, B., 1979).

In self-regulating the process of solving mathematical problems, ideas come into play impacting both motivation and the type of cognitive commitment the student assumes when facing a task. Research has demonstrated how goals take control over processes of attention, memory, and motivation, and thus the results of learning can be quite diverse (Helmke, 1989). Each individual assumes a different position relative to the information to be dealt with. Depending on this assumed position and on the particular situation, individuals will understand to different degrees what function a knowledge schema has in explaining reality. It is evident that acquisition of informational schemata in a school situation does not mean acquiring knowledge.

During the learning episode (Boaekarts, 1996), epistemological beliefs concerning what a student knows about their goals and the possibilities of reaching them takes place. Attention is focused on knowledge structures and on the process of objectivization by which the structures are constructed. A focus of interest is the subject's process of elaborating explanations of their current condition as a student in terms of how they attack the academic task and of the way they justify explanations. It is during this process that the subject assigns an epistemological status to the incoming information during the learning episode.

We can also observe that individuals differ in terms of the degree of awareness they have regarding the nature of knowledge, as has been demonstrated by research into epistemological beliefs (Hoffer and Pintrich, 1997). So, it is assumed that knowledge is systematized information ordered by a function of logical criteria of validity (Kuhn, 2000). It is sustained in formal or empirical evidence and is maintained as valid as long as no contradictory evidence is presented (Miller, 1995). If the organization, coherence and unity of the scientific knowledge taught is different from that existing in the subject's mind, what interactions should take place between the subjective information schema and knowledge?

We may tackle this inquiry assuming the relation object-of-knowledge-subject-of-knowledge where knowledge is an entity, but we may assume that the metacognitive focus could be directed to the knowledge as a process of "knowing", where, ontologically the difference emerges from the fact that knowledge taken as an entity (noun) is taken as a finished object, but any knowledge is the same in the page of a book as in the experience of the student.

PAPER PRESENTATION

Different grades for girls vs. boys? The impact of teachers' perception of students' self-regulation

Poldi Kuhl, Freie Universitat Berlin, Germany; Bettina Hannover, Freie Universitat Berlin, Germany

In this study, we investigated whether boys' lower ability for self-regulated and responsible learning in school might contribute to explaining the well-documented gender differences in grading. A total of $n = 756$ girls and $n = 777$ boys in fourth grade from 78 German primary schools performed standardized tests in German reading comprehension and mathematics. Moreover, teachers provided students' mid-term grades in German and mathematics. Teachers also rated each student's ability for self-regulated learning. Results of multilevel-mediation analyses showed that after controlling for test scores, girls were graded more favorably in German than boys were. This even held true when we additionally controlled for students' ability to self-regulate their learning processes. In mathematics, we did not observe any gender differences in grading or test scores. However, when controlling for students' ability for self-regulated learning, boys featured better grading than girls. These results suggest that teachers' perceptions of students' ability for self-regulated learning partially explain the gender difference in grading in German. In mathematics, however, teachers presumably overestimate and overcorrect the influence of boys' lower ability for self-regulated learning. The results will be discussed with regard to their theoretical implications and their relevance for educational practice.

Different grades for girls and boys?

Examining the role of students' ability for self-regulated learning as perceived by their teachers

Aim:

Numerous studies have documented gender-differences in grading, with girls typically earning better school grades than boys (e.g. PISA 2000, PIRLS 2006, TIMSS 2007). Although this finding has been replicated many times, girls usually do not perform any better in standardized achievement tests or cognitive ability measures than boys do. Hence, boys perform better in standardized tests than would be predicted from their grades.

In order to explain this discrepancy, some authors have argued that standardized tests and their formats favor boys. In contrast, in the present research we investigated the assumption that grades do not only reflect the teacher's perception of a student's performance level and cognitive abilities, but also the teacher's perception of the extent to which a student is a competent self-organized learner. We predicted that as compared to boys, teachers would consider girls to more likely engage in self-regulated learning, i.e. to self-organize, be independent, and manage their

learning processes. As a result, they should grade girls better than boys, after controlling for the impact of competence level.

Methodology:

Study design: Data were taken from the fourth-grade assessment of a longitudinal study on competence development in primary school in Germany. In grade four, we collected data using standardized tests as well as self-report questionnaires for students and teachers in sample schools.

Sample: The sample comprised of $N = 1.533$ fourth graders from 78 German primary schools. About half of the sampled students were girls (49.3%). Students were on average 10.4 years old, with a range between 8 and 12 years.

Instruments: Students performed standardized tests in German reading comprehension and mathematics. Moreover, teachers provided each student's mid-term grades in German and mathematics. Teachers also rated each student's ability for self-regulated learning and self-organized school-related behaviors.

Findings:

Descriptives: Girls earned significantly better grades and test scores in reading comprehension. No gender differences, however, were found with respect to test scores and grades in mathematics. With respect to the ability to regulate and organize learning, teachers rated girls to be more competent than boys.

Multilevel-mediation analyses: Analyses were performed separately for German reading comprehension and mathematics. Even after controlling for their test scores and self-regulated learning ability, girls received better grades in German than boys. As expected, however, the relationship between gender and grading decreased significantly when controlling for self-regulated learning. This suggests that the difference in teachers' perceptions of boys' and girls' competence for self-regulated learning contributes to the gender difference in grades in German.

With respect to mathematics, another pattern of results emerged. In the initial model, no gender differences in grades or test scores emerged. However, there was a significant gender difference after controlling for self-regulated learning competence. That is, given the same competence level and ability for self-regulated learning, teachers graded boys better than girls.

Theoretical and educational significance of the research:

Taken together, students' ability to regulate their learning processes can contribute to explaining the gender differences in grading in schools. Controlling for students' competence for self-regulated learning significantly decreased the gender difference in grades in German. That is, when grading their students, teachers apparently do not only consider students' achievement in terms of performance scores, but also acknowledge girls' stronger self-regulatory and responsible behaviors. In mathematics, gender differences in grades only became apparent when we controlled for test score and ability for self-regulated learning.

From this research we cannot conclude whether girls are in fact better in organizing their own learning than boys. Teachers' ratings could as well reflect gender-stereotypical evaluations or expectations. In future analyses and follow-up studies, we therefore plan to explicitly address teachers' gender-role stereotypes and gender-specific competency expectations, as those might impact their perception of boys' and girls' behaviors. In addition, by additionally considering the self-report data in the student' questionnaires, we aim at exploring the congruency between teacher perceptions and students' self-ratings of self-regulated learning abilities and how they relate not only to grading but also to the development of students' competences and self-concepts.

PAPER PRESENTATION

Fostering students' autonomy and self-regulation: video-analysis of interactional episodes

Valeska Grau, Pontificia Universidad Catolica de Chile, Chile; Sandy Farias, Pontificia Universidad Catolica de Chile, Chile; Barbara Hayes, Pontificia Universidad Catolica de Chile, Chile

The present paper presents the findings of a descriptive study focused on teachers and students interactions within primary classrooms in relation to the promotion of cognitive autonomy and SRL. The data was obtained from analyzing videos filmed for a teaching assessment system implemented by the Chilean Government. 60 videos were randomly selected, considering different levels of performance, content-domain (math or language) and different grades of primary school (1st to 4th grade). A coding scheme was created considering the interaction as a unit of analysis. The codes attempted to describe the ways in which the teachers scaffold the development of cognitive autonomy and

self-regulation. Preliminary findings suggest that teachers do not tend to actively promote these aspects of development in Chilean primary schools. Interactions of low level of cognitive engagement and challenge are predominant. Subsequent analyses are hypothesised to show the relationships between autonomy and self-regulation support and students' developmental stages.

Introduction and aims

The development of autonomy and self-regulated learning (SRL) has been described as essential to children's development, especially in the global networked society. Hence, it is considered a desirable outcome of any educational system. The concept of SRL comes from a sociocognitive perspective, within literature attempting to explain academic achievement in classrooms. It is defined as the capacity to engage actively and constructively in our own learning processes, regulating cognitions, motivations, behaviours and environment (Boeakerts & Corno, 2005). Although SRL have been originally conceptualised as strongly related to metacognition and cognitive regulation, current developments have included motivational aspects, such as agency, autonomy, goal orientation, among others. Increasingly, the models of SRL have been including guidelines to promote this ability in the classroom through the provision of challenge, encouragement of group-work, capacity of self-evaluation and promotion of mastery orientation through adequate feedback (Meyer & Turner, 2002; Pintrich, 2000; Whitebread et al, 2005)

On the other hand, the concept of autonomy support comes mainly from the self-determination theory of motivation. This research has had an important focus on the contexts that foster the development of autonomy, including in educational systems. These studies have mainly focused on observation of classrooms looking at how the autonomy support could be observed in specific teachers' behaviours (e.g. Reeve, 2009; Reeve & Jang, 2006; Reeve et al, 2008; Stefanou et al., 2004). These behaviours, interestingly, overlap to some extent with the advice from the SRL perspective. Bridging the two perspectives together, It has been suggested that classrooms which are autonomy supportive foster and promote students through helping students to set their own goals, seek challenges, direct their behaviours, being more active and flexible, being persistent, and experiencing more positive feelings about their learning (Reeve, 2002). Empirically, there is evidence showing that when teachers and parents are high in autonomy support, students become more intrinsically motivated and more effective in self-regulating their performance (Grolnick & Ryan, 1989)

Looking at the theoretical roots, we have found that both perspectives seem to converge more closely in the concept of cognitive autonomy support, proposed by Stefanout et al (2004). Cognitive autonomy support (in contrast to organisational or procedural autonomy support) refers to the encouragement of students' ownership of their own learning processes and It is related to teachers' behaviours such as asking students to explain their way of thinking or problem solving paths. Despite the efforts to create adequate ways to observe and analyse autonomy and SRL support, up to now the focus has rather relied on the isolated behaviour of teachers (e.g. "the teacher provide feedback to their students", "the teachers listen to their students"), without necessarily looking at the interaction as a unit of analysis. We think that this kind of interactional approach could be very beneficial to looking at the ways in which teachers really engage students in their learning and the ways in which they adapt to students' needs in terms of content knowledge, strategies and motivation.

The main questions guiding the study are the following: Do Chilean primary teachers foster the autonomy and self-regulation development during instructional activities? Assuming that they do, which are the main instructional strategies they use to accomplish it? How do they engage their students in processes of cognitive autonomy and self-regulation? Also, we are interested in the ways in which teachers might adapt their strategies according to students' developmental stages.

Methodology and preliminary results

Design.

This is an exploratory study aiming to describe teachers' strategies and classroom interactions that support the development of autonomy and self-regulation in primary school.

Sample.

60 videos were randomly selected from the videos of the teachers' national evaluation (Docente Mas, hereafter DM). DM is a nationwide system for the assessment of teaching, and includes 4 instruments: a self-assessment, an interview made by a peer, report by third parties and a portfolio, which in turn includes a video-survey of a class (Manzi et al., 2008). In this context 30 language classes and 30 math classes were selected, with different levels of outcome in the whole process of the national evaluation. The videos were from all over the country.

Procedure.

Expert cameramen filmed each teacher. Filming times were agreed in advance and students' attendance was highly encouraged. The cameramen knew in advance the kind of activities the teachers was going conduct, in order to carry

out an adequate record of the lesson. Teachers were asked to conduct the classes as usual, but with an explicit emphasis on addressing students and interacting with them.

Analysis.

Based on the previous work of Reeve et al (2006, 2008), Stefanou et al (2004) in autonomy support and the model of Pintrich (2000) of SRL in educational contexts, a coding system was developed to identify interactional episodes in which teachers are scaffolding the autonomy and self-regulation in their students. Findings.

Preliminary results are showing that there are not many teachers who systematically scaffold autonomy and self-regulation during their classes. Most of them tend to interact with students and give them space to talk, but the interactions are characterised by having a low cognitive level (students have to complete phrases or respond to closed question) with high control from the teachers. These results are probably closely related with the current problems of Chilean education (low results in international evaluations such as TIMSS and PISA and poor results also according to national standards) and is coherent with findings of other studies suggesting that Chilean teachers' instructional patterns are based mainly on transmission of knowledge and practice of basic skills more than the development of metacognition and thinking processes (Preiss, 2009). Conclusions.

The present research contributes to the study of autonomy and self-regulation support through interactions in classrooms. Also, the results are providing some clues about how to foster autonomy and SRL development during the early years of schooling and posit interesting indications for pre-service and in-service teacher training. Further, it opens a discussion regarding the kind of pedagogy that is valued in our culture.

PAPER PRESENTATION

The Impact of Study Programmes on the Dynamic Forces of Self-Direction in Academic Learning

Dirk Bissbort, University of Oulu, Faculty of Education, Finland

As a consequence of the implementation of the Bologna process, the design of study programmes is widely discussed also in the light of goals for academic learning, e.g. advancing students as autonomous learners. This empirical study aims at investigating the impact of study programmes on students' ability of self-directed learning: the influence of 1. study experience of students (number of terms) and 2. level of structuring of the study programmes on the mode of interaction of the dynamic forces on self-direction in learning. For this purpose, the concept 'Dynamic Forces on Self-Directed Learning' was introduced. In questionnaire-based studies (n=879), the modes of interaction of forces within self-directed learning were examined in path analyses for both traditional study programmes and study programmes developed during the Bologna process. The results show that students enrolled in the new BA study programme have a very different motivational and emotional approach to self-direction in their academic learning compared to students in other study programmes. The theoretical significance of this research lies in the development of a new conception of self-directed learning and its dynamic forces that allows a more differential understanding and a more systematic insight in the reciprocity of interrelations of the particular dynamic forces. Regarding the educational significance, the outcomes point to how far changes on the macro level, the design of study programmes, influence students' academic self-directed learning and can therefore serve for developers of study programmes to reflect on the goals and the quality of academic learning when developing programmes.

Aims

As a consequence of the implementation of the Bologna process, the design of study programmes is widely discussed in the light of goals for academic learning, e.g. advancing students as autonomous learners. This empirical study aims at investigating the impact of study programmes on students' ability of self-directed learning: the influence of

1. study experience of students (number of terms) and
2. the level of structuring of the study programmes, on the mode of interaction of the 'dynamic forces' on self-direction in learning. For this purpose, the concept 'Dynamic Forces on Self-Directed Learning', was introduced. It was built from theories and models of self-directed learning (Knowles, 1975; Nenniger, 1999) and its self-regulatory processes (Boeckeaerts, 1997; Efklides, 2004; Kuhl & Heckhausen, 1996; Nenniger, van den Brink & Bissbort, 2009; Schiefele & Pekrun, 1996; Pekrun, Elliot & Maier, 2006; Zimmerman, 1989, 2000), and from concepts of "Approaches to Learning" (as e.g. in Biggs, 1987; Entwistle 2000; Entwistle & Ramsden, 1983; Marton & Säljö, 1976).

The concept focuses on the modes of interaction of the dynamic forces of self-direction in learning and allows outlining the sensitivity of particular forces from changes of other forces like study programme and the effect on students' self-direction in their learning.

Methodology

In questionnaire-based studies (n=879) in Germany, the concept 'Dynamic Forces on Self-Direction in Learning' was validated on basis of samples (n1=146, n2=82, n3=879) of university students of educational science and teacher education. The respective instrument was developed on the basis of scales from current instruments (MLSQ, LIST, BEMSELHIS, SSI, AEQ, ASSIST, ETLQ, IPA-u and LSQ). Next, the modes of interaction of forces within self-directed learning were examined: Scores of the constructs related to the concept 'Dynamic Forces on Self-Direction in Learning' were entered into path analyses. Among the different path models, the following causal structure remained as the most suitable solution (typically RMSEA= .05, CHI=1.46, p=.23, GFI=.99, CFI=.99) to explain the dynamic forces of self-direction in learning (cf. figure 1):

Figure 1: Causal structure of the path model (see appendix)

Dependent factor: Regulation related learning characteristics

Independent factors: Person related learning characteristics.

Perceived learning environment. Continuity oriented learning characteristics. Emotion related learning characteristics

Findings

The major findings from the path analyses carried out for both, traditional study programmes and study programmes developed during the Bologna process, can be shortly described as follows: The influence of dynamic forces on self-direction in learning is characterised by a unique pattern appearing across all path models: differences in the causal structure of dynamic forces influencing self-direction in learning exclusively address the amount of interrelationships between the dynamic forces and their strength of influence on self-direction in learning. In sum, the results show that students enrolled in the new BA study programme have a very different motivational and emotional approach to self-direction in their academic learning, for example, they are less emotionally involved in their mode of self-direction in learning.

Theoretical and educational significance of the research

As advancing active self-directed learning is linked with both, a certain structured study programme and with the study experience acquired therein, these two aspects have to be examined in an integrative rather than in a separate view. The theoretical significance of this research lies in the development of a new conception of self-directed learning and its dynamic forces that opens the view towards a more differential view and innovative understanding in so far as it allows a more systematic insight in the reciprocity of interrelations of the particular dynamic forces. Regarding the educational significance, the outcomes point to how far changes on the macro level, the design of study programmes, influence students' academic self-directed learning and can therefore serve for developers of study programmes to reflect on the goals and the quality of academic learning when developing programmes.

PAPER PRESENTATION

Parental engagement and home support for reading literacy in 14 educational systems in PISA 2009

Pou Seong SIT, University of Macau, Macau; Kwok Cheung CHEUNG, University of Macau, Macau; Soi Kei MAK, University of Macau, Macau

Sixty five educational systems participated in PISA 2009 reading literacy study, which sought to examine factors affecting quality and equity of reading acquisition of 15-year-old secondary students. Amongst the many important factors one pertains to the parents of the sampled students. A total of fourteen educational systems have collected data from the parents of the sampled students, allowing the present study to examine the differential effects of parental engagement and home support on reading literacy performance. Based on a conceptual model depicting how parents' engagement and support of child's reading literacy mediates its effect via provision of home reading resources on the enhancement of reading literacy performance, variables are conceptualized and analyzed using hierarchical linear modeling (HLM). The first finding is that across the fourteen educational systems, the proportion of the between-student within-school reading literacy variance explained by the joint effect of parents' engagement and support of child's reading literacy varies from 0.7% to 3.7% across educational systems. Additional variance attributed to the mediating effect of the provision of home reading resources varies from 0.2% to 2.0% across educational systems. Apart from two educational systems, the mediating effects of the provision of home reading resources are all statistically significant. Preliminary analyses of the parental engagement and home support variables suggest that it is illuminative to analyze the interrelationship of variables in the three high-performing systems using structural equation modeling (SEM). Differential patterns of parental engagement and home support for reading literacy development are revealed, and implications are discussed against literature.

Reading literacy acquisition is an important educational goal in all basic education systems around the world, and parents play a prominent role for its early and continued development both at home and in schools (Clay, 1967; Anderson, Hiebert, Scott, & Wilkinson, 1985). Several decades of educational research into reading literacy development shows that parental engagement and home support are important factors influencing adolescents' reading literacy development (Finn, 1998; Pressley, Billman & Perry, 2007). Amongst the many parental engagement and home support factors under examination by the educational researchers, parents' positive attitudes towards reading-related activities and home provision of appropriate reading resources are construed to be instrumental to the emergent and onward development of reading literacy of young children entering adulthood (Baker, Scher, & Mackler, 1997; Klaua, 2009).

The PISA 2009 Study, an OECD-organized international sample survey of reading literacy in sixty-five countries, renders researchers to examine the effects of parental engagement and home support for reading literacy development from a comparative education perspective. The fourteen educational systems which have parent data included in the present study are: Chile, Croatia, Denmark, Germany, Hungary, Korea, Hong Kong, Italy, Lithuania, Macao, New Zealand, Panama, Portugal and Qatar. The data represents some 2,207,171 parents of 15-year-old students in the fourteen educational systems. In the parent questionnaire there are questions pertaining to parental engagement and support in home and reading activities, namely: (1) highest educational level of parents; (2) number of siblings in household; (3) parents' time spent at home for their own enjoyment; (4) provision of home reading sources for child's use; (5) motivational attributes of parents' own reading engagement; (6) parents' reading activities

when their child attended the first year of primary school; (7) parents' current home and reading activities with children. In addition, students' report of number of books at home is also included.

Scaling of these responses using factor analyses and item response theory (IRT) results in the composition of the four conceptually and empirically clear constructs to interrelate with reading literacy performance: (1) parents' support of child's reading literacy at beginning of primary education (PRESUPP: 9 items); (2) motivational attributes of parents' own reading engagement (MOTREAD: 4 items); (3) parents' current support of child's reading literacy (CURSUPP: 6 items); (4) provision of reading resources at home for child's use (READRES: 6 items).

A conceptual model structuring the temporal order of constructs is then postulated, within this parents' engagement and support of child's reading literacy is manifested in terms of PRESUPP, MOTREAD, and CURSUPP. This model highlights the direct effect, as well as the mediating effect of READRES on reading literacy performance.

Utilizing these constructs, the following four research questions may be answered:

1. Across the various educational systems, what is the frequency distribution of number of books at home, parents' support of child's reading literacy at beginning of primary education, as well as parents' current support of child's reading literacy at home?
2. Across the various educational systems, what are the breakdown statistics of reading literacy performance on: (1) highest educational level of parents, (2) parents' time spent on reading at home for one's own enjoyment, (3) provision of home reading resources for child's use, (4) motivational attributes of parents' own reading engagement, (5) parents' support of child's reading literacy at beginning of primary education, and (6) parents' current support of child's reading literacy?
3. Across the educational systems, what proportion of reading literacy variance can be explained by the joint effects of parents' engagement and support of child's reading literacy, and what additional proportion of reading literacy variance may be attributed to the mediating effects of the provision of home reading resources for child's use, after accounting the prior effects of the economic, social and cultural status of the home and gender of students?
4. For the three high-performing educational systems in reading literacy with parent data, to what extent the effect of parents' engagement and support of child's reading literacy on reading literacy performance is direct and/or mediated by provision of home reading resources for child's use, after accounting for the effects of economic, social and cultural status of the home and gender of student? How to explain the findings in terms of reading acquisition in culturally diverse school settings? For research question 1 and 2, frequency distribution and breakdown of responses to questionnaire questions and on test scores are conducted. For research question 3, Hierarchical Linear Modeling (HLM) is applied to examine the independent mediating effect of provision of home reading resources on reading literacy performance, after accounting for the effect of parents' engagement and support of child's reading literacy, economic, social and cultural status of the home and gender of student. For research question 4, Pearson correlations of the constructs delineated are calculated. Structural Equation Modeling (SEM) is applied to assess the direct effect of parental engagement and home support, as well as the mediating effect of provision of home reading resources which channels the joint effects of parents' engagement and support of child's reading literacy on reading literacy performance.

The first important finding is that across the educational systems, less than 3.7% of the proportion of the between-student within-school reading literacy variance can be explained by the joint effects of parents' engagement and support of child's reading literacy. In addition, less than 2.0% of the variance may be attributed to the mediating effect of the provision of home reading resources for child's use. Apart from two systems, the mediating effect of the provision of home reading resources are all statistically significant ($\alpha=0.05$). The second important finding is that the three high-performing systems with parent data exhibit differential patterns of parental engagement and home support relationships with reading literacy performance. Review of literature against these findings leads the authors to recommend evidence-based practices to revitalize parental engagement and home support for the betterment of reading literacy acquisition in the 21st century.

PAPER PRESENTATION

Does empathy has an effect on literary reading comprehension?

Sofie Henschel, Freie University of Berlin, Germany; Thorsten Roick, Freie University of Berlin, Germany

In the last years, the main predictors for non-fictional (general) reading comprehension have been well investigated (e.g. Guthrie et al., 1999; McElvany et al., 2008). So far, it is not clear which cognitive, motivational and affective aspects effect literary (fictional) reading comprehension. Particularly in the literature (e.g. Oatley, 1994) affective and

emotional components, such as empathy, are pointed out as specific to understand literary and fictional texts, which was not proved empirically yet. Thus, the present study investigates the role of empathy in literary and non-fictional reading comprehension considering the amount of reading literary and fictional texts. About 1.300 ninth graders from German school classes participated in the study. Students completed a test of literary reading comprehension and a test of non-fictional reading comprehension and filled out a questionnaire assessing the individual reading amount and empathy. The analyses show that especially one sub-dimension of empathy, "fantasy", has a stronger effect on literary reading comprehension than on non-fictional reading comprehension, but only for girls. Results reveal no similar differential pattern for boys. The differential effect for girls did not remain stable after controlling for the reading amount of literary and fictional texts. Implications for further research in the field of literary reading comprehension are discussed.

Theoretical Background:

In comparison to the extensive results in non-fictional (general) reading research, there is a lack of studies taking into account the cognitive, affective and motivational determinants in explaining literary (fictional) reading comprehension. While psychological models of text comprehension predominantly focus on cognitive and motivational aspects (Kintsch, 1998), literary didactics emphasize the role of affective components, such as involvement or empathy (Oatley, 1994). So far, there is no empirical evidence underlying the assumption that affective aspects are more important to understand a literary or fictional text than a non-fictional text. Thus, the present study investigates the role of empathy in literary reading comprehension in contrast to non-fictional reading comprehension considering the amount of reading fictional texts.

Empathy, literary reading comprehension and reading amount:

There is evidence that non-fictional reading comprehension and literary reading comprehension are separable and represent partly distinct competencies (Roick et al., in press). It is currently not clear what role empathy plays in literary reading comprehension compared to non-fictional reading comprehension.

Empathy is defined as a motivated competence that "involves the inner experience of sharing in and comprehending the momentary psychological state of another person" (Schafer, 1959, p. 342). The whole construct consists of four cognitive or affective sub-dimensions (empathic concern, distress, fantasy and perspective taking). Recent studies have shown that girls score higher on all sub-dimensions of empathy (Davis, 1983). Despite the central role of empathy suggested by educationalists in theoretical models, researchers have devoted little attention to examining the role of empathy in literary reading comprehension empirically.

Moreover, we know from recent studies that frequently reading literary and fictional texts has a positive effect on empathy (Mar et al., 2006), especially on fantasy empathy (Mar, et al., 2009). Empathy, on the other hand, effects non-fictional reading comprehension positively, but only for girls (Feshbach & Feshbach, 1987). Similar findings are well known for non-fictional reading comprehension and reading amount (Guthrie et al., 1999). Based on recent findings in the field of reading research, we explored three questions:

1. Does empathy has a stronger effect on literary reading comprehension than on non-fictional reading comprehension?
2. Is a differential effect of empathy valid for boys and girls?
3. Is the differential effect stable after controlling for reading amount literary texts?

Method:

About 1300 ninth graders taken from 52 German school classes participated in the study. A cross-sectional design was used. Students' literary reading comprehension (LRC) was measured with nine literary and fictional texts and a total of 62 items ($\alpha=.86$). We used a multi-matrix design with nine booklets, i.e. each student only answered a subset of the test items. Students also completed a test of non-fictional reading comprehension (NRC) which consisted of four expository texts with a total of 18 items ($\alpha=.74$) filled out a questionnaire assessing two sub-dimensions of empathy (fantasy: 10 items, $\alpha=.86$; empathic concern: 10 items, $\alpha=.84$) (Leibetseder et al., 2001) and their amount of reading literary and fictional texts (poems, comics, novels, etc.) for enjoyment (10 items, $\alpha=.81$). Given the nested structure of the data, structural equation analyses were carried out.

Results:

Latent models were used for estimating empathy, LRC, and NRC. Results show that particularly fantasy has a differential effect on reading comprehension ($\beta_{LRC}=.45$, $\beta_{NRC}=.36$, $p<.01$; Wald- $\chi^2(1)=7.43$, $p<.01$) which was not confirmed for empathic concern ($\beta_{LRC}=.11$, $p=.03$, $\beta_{NRC}=.09$, $p=.16$; Wald- $\chi^2(1)=0.15$, $p=.70$). Hence, empathic concern was excluded for further analyses. While we found a differential correlation pattern for girls (Wald- $\chi^2(1)=4.21$,

$p=.04$) we could not confirm it for boys ($\chi^2(1)=0.50$, $p=.48$). After controlling for reading amount literary and fictional texts we did not find support for a differential effect of fantasy on reading comprehension for girls or boys. Moreover the findings reveal that fantasy has no significant effect on literary reading comprehension for boys ($\beta_{LRC}=.17$, $p=.08$) but reading amount has ($\beta_{LRC}=.27$, $p<.01$). On the other hand we found a significant effect of fantasy ($\beta_{LRC}=.22$, $p<.01$) and reading amount ($\beta_{LRC}=.25$, $p<.01$) on literary reading comprehension for girls.

Therefore, we can conclude that fantasy empathy represents no specific factor to understand literary and fictional texts as assumed in literary studies (Oatley, 1994). Although, the results show that fantasy is more important for girls than for boys to understand a literary text. Moreover it is not clear how other sub-dimensions of empathy (i.e. perspective taking, distress) might effect reading comprehension. Thus, further research is needed to explain literary reading comprehension more precisely.

PAPER PRESENTATION

Theoretically Framing Research on Classroom Discourse as it Affects Reading Comprehension

Ian A.G. Wilkinson, The Ohio State University, United States; Hsiao-Feng Tsai, The Ohio State University, United States

The purpose of this study was to examine the theoretical frameworks used by researchers to argue for the benefits of discourse in discussion for promoting reading comprehension. We sought to identify the theoretical constructs invoked by authors of studies of nine prominent approaches to text-based discussions and to examine how they vary by dominant stance toward the text. We developed a taxonomy of theoretical frameworks cited by authors as a rationale for why their approach to discussion should contribute to students' comprehension. We then coded 157 empirical studies of nine prominent approaches to conducting classroom discussion about text using the taxonomy. We found that most researchers invoked a hybrid of theoretical constructs to argue for the benefits of discourse in discussion though Vygotskian theoretical constructs were most commonly used. We also found that theoretical explanations for the effects of discussion varied by dominant stance toward the text (efferent, aesthetic/expressive, critical-analytic). Almost all scholars invoked theories as a 'foundational platform' for their study. Rarely did they explicitly test the theoretical mechanisms they propose as responsible for effects. We conclude with a call for research to test the validity of claims made regarding the mechanisms by which discussion fosters growth in students' reading comprehension.

Aims

The purpose of this study is to examine the theoretical frameworks used by researchers to argue for the benefits of discourse in discussion for promoting reading comprehension. We identify the theoretical constructs invoked by authors of studies of nine prominent approaches to text-based discussions and examine how they vary by dominant stance toward the text. Our goals are to 1) determine the theoretical explanations for the effects of discussions on reading comprehension and their relationship to the goals of discussion as espoused by authors; and 2) examine how theory is being used in research on text-based discussions.

Conceptual Rationale

Recent research supports claims that classroom discourse in small-group and whole-class discussions about text promotes students' reading comprehension. Nystrand (1997) and colleagues showed that features of whole-class discussion were positively related to students' reading comprehension and literary response. These results were largely replicated by Applebee, Langer, Nystrand, and Gamoran (2003) and similar relationships between discussion and students' performance in literacy have been reported in other correlational studies (e.g., Taylor, Pearson, Clark, & Walpole, 2000). In a recent meta-analysis of 42 studies of the effects of various approaches to text-based discussions, Murphy, Wilkinson, Soter, Hennessey and Alexander (2009) showed that many of the approaches were effective at promoting students' literal and inferential comprehension, and some were effective at promoting students' critical-thinking, reasoning, and argumentation about text.

Researchers use various theories to justify their use of discussions to promote reading comprehension and to explain their results. From a cognitive perspective, they argue that discussion promotes active engagement in making meaning from text (e.g., McKeown, Beck, & Blake, 2009). From a Piagetian sociocognitive perspective, they argue that discussion enables students to make public their perspectives on issues arising from the text, to consider alternative perspectives, and to reconcile conflicts among the opposing points of view (e.g., Almasi, 1995). From a Vygotskian sociocultural perspective, they argue that discussion enables students to co-construct knowledge and understandings and to internalize ways of thinking to engage more effectively with new text (e.g., Wells, 2007). From a Bakhtinian dialogic perspective, they argue that the tension and conflict among relative perspectives helps shape discourse and students' comprehension (e.g., Nystrand, 2006).

In this study, we systematically analyze the theoretical arguments made by scholars who conduct research on text-based discussions. We sought to determine the major theoretical explanations for the effects of discussions on reading comprehension and whether the theories varied by the espoused goals of discussion. We also sought to examine how theory is used in the research. According to Dressman (2007), theories can play various roles in the conduct of empirical studies: as a foundational platform to warrant the study, as a frame, as a discursive scaffold, or as the subject of an empirical examination.

Research Methods

Data Source.

Our data source comprised 157 empirical studies of nine different approaches to conducting text-based discussions. We identified these studies by carrying out systematic searches of five major databases. We categorized the approaches according to their dominant stance toward the text (i.e., the goal of discussion): to acquire information on an efferent level (Instructional Conversations, Junior Great Books, Questioning the Author); to respond to literature on an aesthetic or expressive level (Book Club, Grand Conversations, Literature Circles); or to critically analyze the text (Collaborative Reasoning, Paideia Seminars, Philosophy for Children).

Coding.

We developed a 50-item taxonomy of theoretical frameworks cited by authors as a rationale for why their approach to discussion should contribute to students' comprehension. Each item comprised a three-part categorization of 'label-person-construct.' For example, an item under cognitive theory was 'cognitive-Chi-self explanation.' We coded only empirical studies, rather than conceptual descriptions, on the grounds that they would provide a clearer indication of the theoretical warrants for claims made. A single study could be coded in terms of multiple perspectives. Two coders independently coded 17 randomly selected reports, achieving full agreement on 77% and partial agreement on 88%. Thereafter, one coder coded all remaining studies while monitoring agreement with the other coder on a random 10% of studies.

Findings

Results showed that most researchers invoked a hybrid of theoretical constructs to argue for the benefits of discourse in discussion. Across all approaches, Vygotskian theory and its variants were most frequently invoked, with authors citing constructs such 'language as a tool for thought,' 'scaffolding,' and 'internalization' to explain how discussion affords students ways of thinking that they apply to new texts or novel comprehension tasks.

Results also showed that theoretical explanations for the effects of discussion varied by dominant stance toward the text. Studies of approaches that foregrounded an efferent stance were often predicated on a cognitive framework involving some variant of schema theory. Studies of approaches that foregrounded an aesthetic or expressive stance were largely predicated on reader-response theory (e.g., Rosenblatt) and Vygotskian sociocultural theory. Studies of approaches that foregrounded a critical-analytic stance were more eclectic. Researchers frequently cited Adler, Dewey, and Socrates and the importance of engaging with big ideas and educating for critical thinking. These researchers also invoked constructs from schema theory and Vygotskian sociocultural theory.

Theoretical and Educational Significance

Importantly, we found that almost all scholars invoked theories solely as a "foundational platform" (cf. Dressman, 2007) to provide a rationale for their discussion approach and their study. Rarely did they explicitly test the theoretical mechanisms they propose as responsible for effects (a possible exception in this regard is research by Richard C. Anderson and colleagues of Collaborative Reasoning discussions). Studies are therefore needed, preferably microgenetic studies, to test the validity of claims made regarding the mechanisms by which discussion fosters growth in students' reading comprehension.

PAPER PRESENTATION

Development of elementary school teachers' inferential skills and reading comprehension in Chile

Airi Rovio-Johansson, University of Gothenburg, Sweden; Beatriz Figueroa Sandoval, University of Concepcion, Chile; Mariana Aillon Neumann, University of Concepción, Chile

Previous research has found that inferential skills are important in the development of among classroom teachers. According to results of national and international standard tests the reading ability is deficient among adult population in Chile. The purpose of the study is to study and explore the development of elementary language teachers' reading comprehension and competences to use inferential questions (fourth year level) after a training course at a Chilean elementary school. The paper draws on the phenomenography and the variation theory as well as the learning study model in offering 45 elementary language teachers a training course (24 hours and 6 meetings) in reading comprehension and in development of skills in formulating inferential questions. The findings suggest that the Learning study model used to train language teachers reading skills and their ability to formulate inferential questions resulted in improved knowledge and skills among the teachers. On average 60% achieved the highest comprehension level on test 1, and 40% on test 2 and test 3. These results indicate a substantial development of teachers' reading comprehension and skills in formulation of inferential questions and course and effect questions, since elementary teachers have had few chances to improve their reading skills and a systematic and reflexive development of it. Besides, they have lacked didactic practices to be better prepared to generate improved reading comprehension among their students.

Purpose

The purpose of the study is to explore the development of 45 elementary language teachers' reading comprehension and competences to use inferential questions (fourth year level) after a training course by means of the Learning study at a Chilean elementary school. Previous research (Parodi, 1989) has found that inferential skills are important in the development of reading comprehension among classroom teachers. According to results of national and international standard tests the reading ability is deficient among adult population in Chile (OECD, 2000).

Theoretical frame

The study is based on the variation theory: a learning theory originated from phenomenographic research. The phenomenographic research approach is aiming at describing the various ways people understand different phenomena in the world (Marton, 1981). The rational of the learning study is the variation theory, a learning theory developed from the phenomenographic research approach, focuses on learning outcomes and the students' quality learning generated at micro-level of a lesson in the classroom.

Pedagogical teaching and learning models such as the Chinese and Japanese lesson study (Stigler and Hiebert, 1999; Yoshida, 1999; Lewis, et al., 2005) is applied in elementary schools on all levels in many Asian countries. The learning

study (Marton and Tsui, 2004) is a hybrid of the lesson study model according to Marton and Tsui (2004). These models are similar in several aspects: both are based on the idea that a team of teachers should be involved in a continuous working process developing their teaching and lessons, which implies the planning of the lesson, its execution, evaluation and revision. After these steps the teachers start planning a revised lesson to further improve the lesson. The cycle is repeated two to four times, until the group of teachers are satisfied with the results. This means that teachers do not attend classes at the university to improve their skills. Instead the researchers go to the classroom and they teachers and researcher form jointly a "research circle".

The difference between these models is that the lesson study is based on teachers' knowledge from practice, and the learning study, is based on a theory of learning, the variation theory (Marton and Tsui, 2004). The research unit of the variation theory is the student's ways of experiencing and understanding a phenomenon (individual level). The research object is the teachers' qualitatively variation of ways in experiencing, perceiving, and understanding the learning object (collective level). They focus on teaching a subject matter and develop disciplinary/didactic knowledge in preparing the "lesson", based on the learning theory (variation theory) are means to develop teachers' reading comprehension. The group of teachers and researchers share the learning opportunity and the knowledge generated during classroom interaction.

Methodology

The study applies the Learning study model in a training course for 45 language teachers at fourth grade in an elementary school in Chile. Working elementary teachers have had few chances to improve their reading skills and a systematic and reflexive development of it. Besides, they have lacked didactic practices to be better prepared to generate improved reading comprehension among their students.

The training course (6 meetings /4 hours/meeting), including 45 teachers and four researchers, focused on the theoretical comprehension of the concept of inference in general, then on the particular specificity of the cause and effect inferences, then on the application of this knowledge in the asking of inferential cause and effect questions or on the selected texts chosen with the purpose of practicing them. Study material in the training course for the teachers consisted of three textbooks, and texts extracted from science books and history books belonging to a fourth year of elementary school level.

The teachers were split in 10 sub-groups and their knowledge was tested by written tests. Qualitative analysis was used to establish their knowledge to formulate inferential questions. Four tests and three criteria were used to find out teachers' improved knowledge.

Findings

The findings suggest that the Learning study model used to train language teachers reading skills and their ability to formulate inferential questions resulted in improved knowledge and skills among the teachers. On average 60% achieved the highest comprehension level on test 1, and 40% on test 2 and test 3. However, in test 4 only 30% has reached the comprehension highest level. On test 1 "accepted knowledge level" was achieved by 40%, on test 2 and three 50% and on test 4 40%. These results mean a substantial development of teachers' reading comprehension and skills in formulation of inferential questions and cause and effect questions.

Limitations and implications of the results for teacher training program and the procedure of the assessment of teachers' improved knowledge will be further elaborated in the paper.

PAPER PRESENTATION

Changing teaching profession through co-teaching

Anna Rytivaara, University of Jyväskylä, Finland; Jonna Pulkkinen, University of Jyväskylä, Finland

Issues of teacher collaboration and co-teaching are currently being discussed in relation to both policy and practice. Teaching is a changing profession with different phases; nevertheless, it has traditionally been a profession of solitary individuals. This study focused on how co-teaching modifies teaching profession and what factors facilitate or complicate co-teaching. The main data of this paper were the diaries of 30 teachers. The data was analysed with qualitative content analysis. The results of this study indicated that co-teaching lightens teachers' workload due to sharing. Teachers' collaboration seemed to have many positive effects on teaching as well. The study suggests that co-teaching demands reflection, flexibility and common way of thinking about teaching and learning. Co-teaching seems to change both direct and indirect work of teachers. Furthermore, it looks like co-teaching has influence on several dimensions of teachers' professionalism. A critical point of collaboration and co-teaching, however, is common planning time. Implications for teacher education are discussed.

Introduction.

Issues of teacher collaboration and co-teaching are currently being discussed in relation to both policy and practice. Teaching is a changing profession with different phases; nevertheless, it has traditionally been a profession of solitary individuals (Hargreaves, 2000). New era might be emerging, however, since teacher collaboration and co-teaching are mentioned in official documents, such as in the Finnish special education strategy proposal (Finnish Ministry of Education, 2007). The situation in many other countries is probably very similar to Finland, where special education teachers use only 7% of their teaching time in general education classroom together with another teacher (Takala, Pirttimaa, & Törmänen, 2009). The main idea of this inclusive act is to provide pupils with flexible support, contrary to present, rather heavy special education system. However, there is very little evidence of how co-teaching actually affects on teaching profession. Professionalism can be divided into three dimensions: technical culture, service ethic and professional commitment. The last one of these includes commitment to teaching, the subject matter and continual personal growth (Day, 2002). Furthermore, teachers' work can be divided into direct work, related to teaching, and into indirect work, which is related to work teachers do outside lessons (Takala et al., 2009). In co-teaching, unlike in the traditional working model, teachers share both of these, wholly or partly. It is, therefore, important to focus in more detail on teachers' views on collaboration and co-teaching. The aim of this paper is to examine how co-teaching modifies teachers' work, and what factors facilitate or complicate co-teaching.

Methods.

This research is part of a larger project which aims at developing new forms of support at schools. The project is funded by the Finnish Board of Education. The subproject from which the data was collected for this paper, focuses on teacher collaboration and co-teaching. It includes eight participating municipalities in Central Finland with total of 850 elementary school teachers. In the first phase of the study, all the teachers were sent a questionnaire. The focus of this paper is on the second phase of the study, in which we got 22 applications from teacher teams who were willing to volunteer to experiment intensive co-teaching for nine weeks. 11 teams, 30 teachers, were selected for the experiment on the basis of the aims the teams had set for co-teaching. The project funding made it possible to pay the teachers 4 hours of work a week for their co-planning and reporting, which was in addition to their regular working hours (~24 lessons plus 3 hours for indirect work a week). All the teachers were informed about the research at the project announcement. Furthermore, all the teachers selected to the project signed an informed consent for us to use the data (diaries, interviews) for research purposes. In addition to actual working together, the teachers were committed to fill in a short daily questionnaire, and to keep a weekly diary. In addition, the researchers visited each of the schools to make tentative interviews and to get acquainted with the teachers. Teachers' diaries are the main data of this paper. The data was analysed with qualitative content analysis (Mayring, 2000). Further analysis of the data is under process.

Results.

All the teachers had rather similar experiences regarding the effects of co-teaching. Teachers talked about self-reflection; how it is possible to observe another teacher at work and to learn from it, as well as to ponder one's own teaching. Co-teaching also gave teachers more time to observe the pupils and their learning more closely while the other teacher took responsibility for actual teaching. Co-teaching also encouraged teachers to use instructional strategies which they could not use when working alone. Most of the teachers seemed to enjoy co-teaching. Some teachers, however, were more willing than others to share their work with their colleague, whereas some kept rather

fixed roles during the common lessons. A remarkable challenge for the teachers was to find a common planning time with their co-teachers. For the more flexible teachers, however, even the common planning time was kind of an extended and enjoyable part of co-teaching. Based on the differences in teachers' interviews, it seemed that success in co-teaching was based on common trust and teachers' open attitudes towards new ways of working. These teachers also expressed common way of thinking about teaching and learning. They emphasized flexibility at work as well.

Conclusions.

The results of this study indicate that co-teaching lightens teachers' workload due to sharing. Teachers' collaboration seems to have many positive effects on teaching. The results are consistent with current research (Pfeifer & Holtappels, 2008), but our study adds new knowledge about the co-teaching. The study suggests that co-teaching demands reflection, flexibility and common approaches to teaching. Co-teaching seems to change both direct and indirect work of teachers. Furthermore, it looks like co-teaching has influence on several dimensions of teachers' professionalism. A critical point of collaboration and co-teaching, however, is common planning time. This finding corresponds to the findings of Carter, Prater, Jackson, and Marchant (2009). All-day working model could be a suitable solution for this problem. The implication for teacher education is how to support this kind of new professionalism. The other issue is to consider such criteria for the admittance to the teacher education that would result in student teachers and professional teachers, who are willing to share their classroom with another professional.

PAPER PRESENTATION

How cognitive activating are novice teachers' lessons compared to those of experienced teachers?

Corinne Wyss, University of Education Zurich, Switzerland; Titus Guldemann, University of St Gallen, Switzerland;
Mirjam Kocher, University of Education Zurich, Switzerland; Anneliese Elmer, University of St Gallen, Switzerland
Matthias Baer, University of Education Zurich / University of Zurich, Switzerland

As a result of the unsatisfactory effectiveness of Swiss teacher training (Oser & Oelkers, 2001; Oelkers & Oser, 2000), for the first time in the history of Swiss teacher training, standards were formulated which attempt to conceive the competences of teachers in a concise manner based on defined ideals. Embedded in this context and supported by the Internationale Bodensee Hochschule (IBH) and the Swiss National Science Foundation (SNF), our research project examined training and job experience oriented towards professional practice. Additionally, the impact of the first year in profession on novice teachers' competences was investigated. For the three years of teacher education, the results show an overall increase in teaching competences for each year. However, for the first year in profession almost no further progress in novice teachers' teaching competences was found and the level of students' cognitive activation in the 82 videotaped lessons taught by them at the beginning and at the end of their first year after graduation rather seems to be low. Due to these observations, tracing the quality of novice teachers' competence to cognitively challenge their students in a lesson became the specific focus in continuing the research project. On the basis of Klieme, Pauli & Reusser (2003), Blömeke et al. (2006) and Danielson (2009), we developed and applied procedures for analyzing the 82 lessons. Accordingly, the videotaped lessons of experienced teachers with ten and more years of successful teaching as a reference group were analyzed. Results of these analyses will be presented.

As a result of the examination of the effectiveness of Swiss teacher training in the 1990s by Oser & Oelkers (2001; Oelkers & Oser, 2000), it became evident that the training of teachers in Switzerland was not as good as previously

imagined. Oser's (2001, p. 310) conclusion that "what develops in the heads of candidates for the teaching profession is not professional ability and mastery, but merely isolated pieces of knowledge" (see also Wideen, Mayer-Smith & Bloom, 1998) was disconcerting. A great deal has changed since then. Fuelled by the unsatisfactory effectiveness of Swiss teacher training, the turn of the millennium saw the emergence of "Pädagogische Hochschulen" (educational universities) in Switzerland. Whereas teachers had been trained in so-called Lehrer/innenseminaren - pre-service training at higher secondary level - training of teachers occurs now, after the reform, at the tertiary level. Moreover, influenced by initiatives of teachers' associations and state educational institutions in America and Australia (cf. for example Wilbers, 2005, 135 ff; Keller, 2002; Dalla Piazza, Keller & Lienhard, 2002), for the first time in the history of Swiss teacher training, standards were formulated which attempted to conceive the competences of teachers in a concise manner based on defined ideals. Teacher training should no longer take place according to the principle of "anything goes", as Oelkers stated, but should rather be oriented towards a total of ten professional standards. The new educational universities adopted these standards as the maxim of their training (PHZH, 2002; Jurt, 2005; Baer et al., 2008). Referring to these standards new curricula and examination regulations were developed, the Bologna declarations were implemented in a step-by-step fashion, the Swiss educational universities learned to devise and pursue longer-term development strategies, and the question of effectiveness and quality, of achieved standards and acquired competences, became a focal point of interest. Reforms of the degree courses, which were designed only a few years ago, are meanwhile already underway (Keller, 2006).

Embedded in this context and supported by the Internationale Bodensee Hochschule (IBH) and the Swiss National Science Foundation (SNF), our research project examined a key area of the teacher training degree course, namely training and job experience oriented towards professional practice. Additionally, the impact of the first year in profession on novice teachers' competences was investigated. Both perspectives aimed to provide information about the acquisition and quality of teaching competences of prospective and novice teachers at the primary school level (grade 1 to 6 in Switzerland). A group of expert teachers with many years of successful teaching experience constituted the reference group.

The results of the research project give rise to optimism: For the three years of teacher education, the results show an overall increase in teaching competences for each year (Baer et al. 2007, 2009, in prep.; Larcher et al., 2010; Kocher, Wyss, Baer & Edelmann, 2010), also with regard to the dimension "cognitive activation". However, there are two "but": (1) For the first year in profession almost no further progress in novice teachers' teaching competences could be found. (2) Although student teachers' competence to cognitively activate the students in their videotaped lessons significantly improved throughout teacher education, questions and problems novice teachers' – in their first year after graduation – let the students work on do not seem to be challenging enough due to rather low cognitive activation levels. These observations drew our attention in continuing the research project.

Tracing the quality of novice teachers' competence to cognitively challenge the students in their lessons became the specific research focus. Students' cognitive activation is central for teaching quality. According to Stein et al. (2003) and Hiebert and Grows (2007), adequate cognitive challenge is – besides time on task – a very important factor for students' success in learning. Together, the two factors lead to deeper understanding and more sustained learning due to more profound information processing and problem solving activities by the learner. Therefore, it is imperative that teachers are able to pose adequate questions and problems to challenge students' cognitive activities.

In pursuing the research question whether novice teachers are competent enough to challenge students cognitively, we analysed 82 videotaped lessons which novice teachers taught at the beginning, respectively the end of their first year in profession. Our research questions are: How do novice teachers arrange the important start phase of a lesson (first 10 minutes)? Of what quality are the questions and/or problems novice teachers pose their students (at the beginning of a lesson)? In which ways do students participate in the learning activities of the videotaped lesson? How cognitively challenged are they? How are the learning interactions arranged between teacher and students and among students? Of what quality for students' learning processes are they? How do novice teachers support the learning processes of their students? Is their support cognitively beneficial enough for the students?

On the basis of Klieme, Pauli & Reusser (2003), Blömeke et al. (2006) and Danielson (2009), we developed and applied procedures for analyzing the videotaped lessons, respectively for transforming qualitative data into quantitative data. The videotaped lessons of experienced teachers with ten and more years of successful teaching as a reference group were analyzed accordingly. First results show that the cognitive activation level is astonishingly low. Furthermore, novice teachers predominately pose many small and close questions in a lesson which are answerable by the students with few cue words only. More detailed results, especially those from comparing novice and experienced teachers and from comparing data from the first and the second measurement point will be available by the time of the conference.

PAPER PRESENTATION

Teachers' motivations for teaching in higher education

Gerda Visser-Wijnveen, Leiden University, Netherlands; Ann Stes, University of Antwerp, Belgium; Peter Van Petegem, University of Antwerp, Belgium

Motivation is a powerful, but rather neglected force in teaching at higher education institutes. In the strive for excellence in teaching a better understanding of academics' motivations for teaching is necessary. In this mixed-method study a questionnaire was presented to 283 academics and semi-structured interviews were conducted with 18 of them. Six different clusters of teachers were identified with regard to motivation: expert teacher, moderate teacher, subject specialist, passionate teacher, low commitment teacher, and weak teacher. The teachers in the various clusters differ on their perceived personal effectiveness, interest, and effort for teaching. Interview data revealed the competitive function of research and the importance of the subject they have to teach.

Aims

One of the major issues in higher education is the quality of teaching. As staff/student ratios increased over the decades, while at the same time international attention to teaching and student learning expands, enormous efforts have to be made to find ways to help academics develop their teaching quality (Schimank & Winnes, 2000). Next to someone's capacities his or her motivation greatly influences the actual performance (Ambrose & Kulik, 1999). If we want the teaching body of universities world wide to improve we need to address this issue and see what different motivations academics hold for teaching and how we can use this for the benefit of universities, academics, and students. In the concept of motivation we include aspects of self-efficacy, interest, and effort. We aim to distinguish between various forms of motivation for teaching by means of clustering.

Methodology

On a voluntary basis 283 academics from various higher education institutes returned a questionnaire on motivation for teaching. Interviews were conducted with a small sample that participated in a one-year instructional development programme for novice teachers aimed to raise professional standards with regard to classroom practice. For 18 academics both questionnaire and interview data were available. The questionnaire on motivation was developed on the basis of three previous questionnaires: a self-efficacy/motivation questionnaire by Trigwell, Aschwin, Lindblom-Ylänne, and Nevgi (2004), the Intrinsic Motivation Inventory (Deci & Ryan, n.d.) and the Teacher Efficacy-questionnaire by Soodak and Podell (1996). Four scales contributed to the construct of 'motivation for teaching': personal effectiveness: context, personal effectiveness: general, interest, and effort. A semi-structured interview was conducted with all participants of a one-year instructional development course for novice teachers organized at the University of Antwerp in 2005-2006. This interview focused on the motivational themes of perceived personal effectiveness, interest, and effort for teaching. A hierarchical cluster analysis was performed on the questionnaire data to explore homogeneous clusters of cases within the data. Average linkage within groups and squared euclidean distance were used to calculate the mean distance between all possible cluster pairs. A one-way ANOVA was performed to see whether the clusters differed on the four scales. The Tukey B-test was used as post-hoc test to identify which clusters differed from each other on which scales. All interviews were independently analysed by two researchers. Afterwards, the analyses of both researchers were compared and adjusted to a combined codebook including the variation identified by both researchers. Ultimately, the teachers were assigned to the final categories.

Findings

The hierarchical cluster analyses showed six clusters with a meaningful difference. On all scales the clusters differed significantly. On the basis of their properties the six clusters can be characterised as follows: Expert teacher: high capacities, interest, and effort (n=130). Moderate teacher: moderate capacity and interest, and high effort (n=36). Subject specialist: high capacities for specific subject, and very high effort, moderate interest and general teaching capacity (n=46). Passionate teacher: capacity below average, high interest and effort (n=54). Low commitment teacher: relatively low capacity, moderate interest, and low effort (n=9). Weak teacher: low capacity, low interest, and moderate effort (n=5).

The combination of the quantitative data and the qualitative analysis led to more detailed pictures of the six clusters. The number of interviewed participants in the six clusters varies between 1 (F) and 6 (C). For 'personal effectiveness' the main division was on the level the teachers estimated themselves, being good, moderate, or weak. The argumentation for these estimations varied from 'experience' (low) to 'content knowledge' (low or excellent) and 'teaching practice' (transmissive or student-centred). The theme 'interest' was divided in four categories:

content/negative (no interest, because of subject), content/positive (interest, because of subject), teaching/content (interest, because of teaching of specific subject), teaching/process (interest, because of the process of teaching). The theme 'effort' was related to respondents' perceptions of their professional identities: researchers put lowest effort, teacher/researchers tried to balance their effort for both tasks, teachers dedicated most effort to teaching.

Summarised, the qualitative analysis showed the following characteristics: Cluster Personal effectiveness: context Personal effectiveness: general Interest Effort A Good Good Teaching/process and Teaching/content Teacher/Researcher and Teacher B Moderate or Good Moderate or Good Teaching/content Teacher/Researcher C Moderate or Good Moderate Teaching/content and Teaching/process Teacher/Researcher D Low Low Teaching/content and

Content/positive Teacher/Researcher E Low Low Content/positive Researcher F Low Low Content/negative Researcher Significance Motivation is easily overlooked as a significant factor in the quality of teaching. Especially programmes for instructional development focus mainly on competencies of teachers. If motivation is taken into account this is rarely diversified in rationales for motivation. Our research showed that a high effort was characteristic for most teachers; only one group was not willing to put that much effort in teaching as they considered research far more important. Dividing time and effort between research and teaching was, nonetheless, an issue for many teachers. For some teachers their motivation is highly affected by the subject they have to teach, either in a positive or negative way. For other teachers self-efficacy stands out: for example a lower self-efficacy for novice teachers. It would be interesting to investigate in future research in what ways the different rationales for motivation influence teachers' professional development.

PAPER PRESENTATION

Progress and stillstand? – Teaching competences in teacher education and first years in profession

Matthias Baer, University of Education Zurich / University of Zurich, Switzerland

There is empirical evidence enough to assume that teaching quality is strongly related to students' learning outcomes. Therefore, teachers should become experts in their fields, first of all by an effective teacher education, but also by learning through regularly experiencing teaching when they have started to work in their profession. However, still little is known on an empirical basis about the effects of teacher education and regularly teaching a class after graduation.

In our paper, we shed a light on the acquisition of teaching competences. With experienced teachers as a reference group, the focus of interest was the longitudinal analysis of teaching competences from the beginning up to the end of teacher education and into the first and second year as a novice teacher.

We report on three of totally eleven data collection instruments: (1) an online-questionnaire for self-estimating one's own teaching competences, (2) vignettes to trace competences for planning and implementation of teaching, and (3) videos of school lessons taught by the subjects of the research project. Each instrument was applied with student teachers, novice teachers in their first two years and experienced teachers with many years of successful teaching. In addition to the quantitative analyses, procedures for transforming qualitative data into quantitative data were developed and applied.

The results for the three years of teacher education show an overall increase in teaching competences for each year. However, for the first two years in profession surprisingly almost no further progress could be found.

PAPER PRESENTATION

Teachers seek but do not offer help: Factors which enhance or hinder teachers' help seeking

Kati Makitalo-Siegl, University of Jyväskylä, Germany; Anna-Maria Mekota, University of Munich, Germany; Silvia Schulz, University of Munich, Germany

Adult help seeking is influenced by numerous variables and deciding to seek help is not always an easy step. While several help-seeking studies in school and adult education exist, there are only few studies concerning teachers' help seeking directly at their workplace, especially focusing on teachers at their different career stages. This study investigates less and more experienced teachers' help-seeking behaviour and aims to identify which factors prevent or enhance help seeking in schools. Qualitative content analysis of 10 teachers' interviews (primary and secondary schools) reveals that a teacher, who is facing a problem, has to take a first step to seek help. In general, the teachers do not offer help to their colleagues without a help request, but a principal can take the role of a help-giver without receiving a help request from teachers. Teachers have several informal help sources in schools and outside their schools; for example former student fellows who are teachers at other schools. These help sources are selected based on the personal relationship or help-giver's expertise, status or willingness to give help. The help source is more often perceived as equal or higher in status as the help-seeker. For this reason, experienced teachers might find it more difficult to seek help than novice teachers. In order to design a successful support system for teachers, we suggest that the factors enhancing and hindering teachers' help seeking with the intergenerational aspect should be considered.

By 2015 over a million primary and secondary education teachers will have to be recruited and trained in Europe (Education and training, 2010; Report based on indicators and benchmarks, 2006). One third of all teachers are aged over 50 and many senior teachers are retiring as early as possible. At the same time a significant number of novice teachers leave their profession during their first years, due to various reasons, such as disciplinary problems, high workload, and low income. A mass escape might cause a shortage of trained educational personnel in Europe. Several support or mentoring systems have been implemented, especially for novice teachers, but the studies on help seeking, however, show that teachers do not seek help from formal sources (Wills, 1983; Tellez, 1992).

The growing number of teachers leaving their profession indicates a lack of adequate support. Therefore, a focus should lie on the identification of the factors that enhance or hinder teachers' help-seeking behaviour at different stages of their careers in various school levels in order to provide adequate help for teachers when they need it. Comparing the teacher profession with other professions, one major difference is evident: novice teachers are expected to be fully ready for the demands of teacher profession (Lortie, 1975). Therefore, a teacher who is seeking help may risk losing his face. This aspect might not only set a barrier for novice teachers to seek help, but also for senior teachers who are regarded as being an expert. The avoidance of help seeking might also be a way to assure the teachers' abilities and selfworth in the classroom (Retelsdorf et al., 2010). According to Glidewell et al. (1983), teachers' interdependency and the norms of autonomy and equality are likely to discourage teachers to seek and receive help. They also state that a request of help implies low status of a help-seeker. Furthermore, people are more likely to seek help from someone of equal or higher status than from one of lower status (Shapiro, 1983).

So far, there are hardly any studies focusing on teachers' help-seeking behaviour regarding the intergenerational aspect. In this study we investigate teachers' help-seeking behaviour at various stages of their career in different school levels focusing on the factors which enhance or hinder teachers' help seeking.

Method

Teachers were recruited individually and joined the study voluntarily. The data was collected by individual interviews with 10 teachers from primary- and secondary-school levels (one elementary school, two high schools and one special education school). Four teachers had less than 5 years of teaching experience after the pre-service education and they were named novice teachers (mean years of teaching experience = 1.4). Another four of the participants (named senior teachers including principals) had more than 20 years of teaching experience (mean years of teaching experiences = 30.5). Two so called middle-teachers had less than 20 years, but more than 5 years teaching experience (mean years of teaching experience = 7.5). The interviews were transcribed and content-analysed. The help-seeking analysis focuses on the following questions: Who takes the initiative when problems arise? Whom do they ask for help? What kind of persons and in what kind of situations do teachers ask for help? On the basis of these questions we will identify different kinds of help sources - informal or formal - and compare the status of help-giver and help-seeker.

Results

Based on the teachers' interviews, there is a common understanding that the person who needs help should ask for it. A principal, who has the highest status at the school, can be the one, who offers his help without a teacher requesting it. Our preliminary results show that the teachers in this study, sought help from informal sources, such as their colleagues in and outside their schools, family, and former teacher counsellors (see also Tellez, 1992; Wills, 1983). The colleagues from outside the school are usually former student fellows from pre-service or continuing education who are perceived more as friends than colleagues. Using more informal sources than formal sources seems to be common, because schools rarely have a formal support system (a system which is organised by the school administration and is taking place regularly) for novice or other teachers. Close and long-term relationships and trust enhance teachers' help seeking both in and outside their schools.

The data analysis reveals that the teachers are selective whom they ask for help. They seek help from people they perceive as friendly and caring and who are willing to help. The selection is based also on the help source's expertise. The results of our data analysis support the results of the earlier study by Shapiro (1983), that people are less likely to seek help from someone of lower status than from one of equal or higher status. For example, the teachers of this study turned to their former fellow students which are perceived as equal of status. There were no indications in the data that more experienced teachers sought help from their younger colleagues. It seems that the novice teachers possess positive expectations for collegial support, whereas the experienced teachers perceive a teacher as a lonely fighter, which might affect on their help-seeking behaviour. The teachers at the elementary school had more formal support than in the other school levels, which might affect on their perception of help seeking as appropriate coping behaviour. More results on the teachers' help-seeking behaviour at different stages of their career in various school levels will be presented and discussed in the conference presentation.

Discussion

As the preliminary results reveal, teachers' needs and demands varies at their different stages of their career as well as in different school levels. Help seeking should not be seen as a sign of weakness, but of appropriate and professional, coping behaviour. A successful support system is strongly needed: Therefore, the identification of the different elements, which affect teachers' help-seeking behaviour in their schools as well as the intergenerational aspect, should be taken into account and will be discussed in the conference presentation. Furthermore, we will consider the challenges and the possibilities to utilise the technology as a part of the successful support system based on the results of this study.

PAPER PRESENTATION

Effectiveness of a professional development intervention in the field of text-picture integration

Katrin Lintorf, Technical University of Dortmund, Germany; Nele McElvany, Technical University of Dortmund, Germany; Camilla Rjosk, Technical University of Dortmund, Germany; Jurgen Baumert, Max Planck Institute for Human Development, Germany; Wolfgang Schnotz, University of Landau, Germany; Holger Horz, University of Frankfurt, Germany; Mark Ullrich, University of Koblenz-Landau, Germany

Many textbooks contain instructional pictures such as graphs. Unfortunately, students often have difficulties to correctly integrate information from the two sources, texts and pictures. In this situation teachers need professional knowledge to diagnose such problems and to offer the necessary support. Within the expert paradigm of teacher research, professional knowledge is assumed to be learnable. So the aim of the present study was to develop and evaluate a professional development intervention in the field of text-picture integration. Two video based interventions were developed. Both presented text-picture related information with according examples. Additionally, the video content was deepened by exercises with feedback. The experimental group received information about relevant characteristics of students and the instructional materials as well as processes of text-picture integration. In contrast, the control group received a placebo intervention with only very general text-picture integration related information. Both interventions were examined in a pretest-posttest design. The results show that the chosen approach was highly successful since the experimental group showed a significant higher gain in instructional relevant knowledge than the control group. This knowledge gain was neither moderated by aspects of the instructional quality of the video nor by prior knowledge in terms of knowledge about text-picture integration. Instead, contradictory to the expectations, a higher work experience was associated with lower knowledge gains. The implications of these highly relevant results will be discussed with regard to teacher education and further research.

Aims

Most school textbooks contain instructional pictures such as graphs. The ability to correctly integrate the information from both sources, texts and pictures, is a critical condition for learning (Schnotz & Bannert, 2003). But students often

have misconceptions about the interpretation of instructional pictures. Unfortunately, many teachers are unaware of this. Indeed, neither is text-picture integration systematically taught in teacher education in Germany, nor is it recognized as an important instructional goal (McElvany et al., 2009).

However, theories of professional development emphasize that it is teachers' expert knowledge that constitutes the professional standing of teachers (Shulman, 1986). In the past, empirical support for this assumption was only gathered with indirect measures of knowledge (e.g. degrees: Hawkins, Stancavage, & Dossey, 1998). Recent studies show that the promising results of these studies may also be transferred to performance measures (e.g. instructional quality: Hill et al., 2008).

Integral part of this focus on knowledge is the assumption that professional knowledge is learnable (Berliner, 2001). In fact, results from inservice teacher education document the overall effectiveness of professional development programs (Smith & Gillespie, 2007). Whereas the effects of structural aspects are examined but not yet empirically proven (e.g. duration etc.: Kennedy, 1998), a differential effectiveness according to individual characteristics of the participants has not been studied. However, interpreting the teacher as a learner in this setting makes the application of results from instructional psychology reasonable. Most prominent results in this area of research imply that present learning depends on instructional quality and prior knowledge (Weinert & Helmke, 1995). Thereby the instructional quality is usually examined along different aspects and prior knowledge may be understood as knowledge in the relevant domain or as a more general expertise, e.g. work experience.

With regard to the theoretical background and the presented empirical results the following research questions were addressed:

- 1) Does the described professional development intervention enhance the knowledge of inservice teachers about the field of text-picture integration?
- 2) Within the intervention, is a gain in knowledge also positively associated with prior knowledge and the quality of instruction?

Methodology

The analyses are based on data of the German project BiTe, which examines student competencies about text-picture integration and teacher knowledge about the key aspects of this ability. As part of the project a video intervention was developed, which was administered to 58 Biology teachers. 36 of them took part in a text-picture integration related intervention whereas the other 22 teachers received a placebo intervention. Both videos presented text-picture related information with according examples. Additionally the video content was deepened by exercises with feedback. The text-picture related intervention contained information about relevant characteristics of the learner and the instructional material as well as processes of text-picture integration. In contrast, the placebo intervention contained only general text-picture related information. In an experimental design, knowledge gains were measured by means of a pretest-posttest design. The knowledge test was developed and piloted in an earlier phase of the project. It consisted of 20 multiple choice items, which measure knowledge about pictures, about instructional processes, about characteristics of students, and about processes of text-picture-integration.

Findings

Regression analyses and effect sizes were used to analyze whether the text-picture integration related intervention enhances the teachers' knowledge and respectively, whether this knowledge gain differs from that of the control group. The results revealed that under control of prior knowledge in the field of text-picture integration the posttest knowledge of the experimental group was significantly higher than that of the control group ($b = .51$, $p = 1.04$). In order to test potential moderators of the knowledge gain, interaction terms of the experimental condition with potential moderators were included in the regression equation. Neither teacher ratings of the instructional quality of the video, nor the prior knowledge in the relevant domain moderated the knowledge gain. Yet, work experience proved to be a significant moderator ($b = -.55$, $p = .010$). Contradictory to the expectations, teachers with a longer work experience showed significantly lower knowledge gains.

Theoretical and Educational Significance

The presented findings clearly show that the implemented intervention in the field of text-picture integration was very successful. Furthermore, the absent moderating effects of the instructional quality and prior knowledge in the relevant domain should be considered a positive sign in that the intervention had a uniform effect on all teachers. On the other hand the moderating effect of work experience might be a question of age. These results are highly relevant. From a theoretical point of view they underline the assumption that professional knowledge is learnable and that it shows a manifestation in performance measures. From a practical point of view the evaluated intervention

appears to be a promising approach for inservice teacher education by closing the substantial gap in text-picture integration in teacher education.

PAPER PRESENTATION

Teacher research in Dutch secondary education: Effects and issues of quality

Jacobiene Meirink, Leiden University, Netherlands; Paulien Meijer, Utrecht University, Netherlands; Helma Oolbekkink-Marchand, Radboud University, Netherlands; Ditte Lockhorst, Oberon research institute, Netherlands

This study describes an empirical exploration of three Dutch projects in which secondary education teachers (learn to) research their own practice in collaboration with research institutes within universities. These three projects are exemplary for a recent movement of doing research on education in close collaboration between teachers, schools, and universities. The study shows the results of the three projects for both teachers and schools, and how these results are related to organizational conditions within the three projects. Perceptions of revenues of 48 teachers and 17 managers of 11 schools were gathered with interviews. These data were analyzed using the criteria for practitioner research of Anderson and Herr (1999), consisting of five types of validity that together provided an indication of the quality of the teachers' research. The projects showed results mainly on the level of the individual teacher. Teachers reported development of their knowledge and skills with respect to doing research, a more critical attitude, and consciousness of and (intentions to) change of teaching performance. To a lesser extent results on school level were reported. Organizational conditions appeared to be related to results on school level, not to results on the level of individual teachers. The study concludes to state that, if these type of projects are about to lead to the collaborative development of more scientifically accepted knowledge, more attention needs to be paid to the dissemination of knowledge as well as to the quality assurance of the research performed.

Aims & research questions

Practitioner research, teacher research, inquiry learning, self-study: teacher research is popular in literature on teaching and teacher education. Recently, in Dutch secondary education various teacher research projects were financed to foster teacher professional development. Teacher research can be an effective way of professional development. This links to the idea of the teacher being the 'active knower' instead of using knowledge of others (Cochran-Smith & Lytle, 1999, Cochran-Smith & Demers, 2008). Although teacher research projects seem to be promising, in literature on teacher research only a few studies can be found that actually describe the effects and the quality of practitioner research (Wilson and Berne, 1999). In this study, we describe three teacher research projects that are exemplary for the recent movement in the Netherlands of doing research in education in a context of close collaboration between teachers, schools and universities.

Two research questions will be addressed: (1) What are the results of teacher research both for teachers and schools? and (2) how do these results relate to the organizational characteristics of the initiatives around practitioner research in schools.

Theoretical framework

Most teachers search for ways to improve their teaching practice. For this purpose, teacher research in which teachers are actively involved in knowledge generation can be an effective method (Cochran-Smith & Lytle, 1999; Henson, 2001; Burton & Bartlett, 2005). Coppola (2007) refers to scholarship when research and teaching coincide. Similar to scientific research, teacher research has to meet quality standards. Anderson and Herr (1999) described different validities which can indicate the quality of teacher research in the context of the school. These validities provide a useful method to describe teacher research outcomes, beside the individual outcomes which are often the only outcomes being described. We used four of these validities to describe the outcomes of the research projects in our study. Outcome validity was used to determine whether the research undertaken resulted in meaningful outcomes for teachers and schools. Democratic validity concerned the involvement of different parties in the problem under investigation, for instance students or colleagues. Catalytic validity illustrated if teachers required a better understanding that transformed their own knowledge and behavior and the knowledge and behavior of other parties. Dialogic validity demonstrates the way in which dialogue with peers was developed.

Methodology

Each project consisted of three to four schools in which teachers participated in research projects. In total 48 teachers and 17 school leaders were involved in the data collection. Semi-structured interviews with teachers and school leaders were used to examine the outcomes of these projects and how these outcomes might be related to organizational characteristics. The four validities described previously were used to analyze the data regarding the first research question. Quotations in the interviews relating to the different validities were identified, grouped and labeled by two researchers independently. Next, they discussed these groupings/labels until they reached consensus. Per type of validity the researchers calculated frequencies of the quotations per validity and per school. Relevant quotations from the interviews that related to the way teacher research was organized in schools were analyzed in a similar procedure.

Findings

The results of the three initiatives around practitioner research in schools are described in terms of the four validities. In general the projects were beneficial for the individual teachers who mentioned outcomes like an increase in research knowledge and skills, critical attitude to their own teaching practice and an intention to change their teaching practice. Results for the school focused on the development of a critical attitude towards school policy, but were reported less often. Concerning the organization of the initiatives no relation was found between the results at teacher level and the organization of research within the school. However, a relation between the way the project was organized and the results at school level was found. In schools where teachers reported a change in school culture explicit attention from school management, and sometimes teachers themselves, for the positioning of the projects was realized. Furthermore, the topic of research also related to outcomes on school level. In schools where teachers perform research which is closely related to school policy and management issues, a more critical attitude towards policy in general was reported. Theoretical and educational significance of the research This study shows that the quality validities of Anderson and Herr can be used to describe the outcomes of teacher research projects. Together, these validities provide a more comprehensive framework of analysis for effects of teacher research compared to merely determining direct outcomes for teachers. Furthermore, an in-depth study of teacher research and its results and quality, gives clues for the organization of this type of research in schools and universities and for organizing teachers' professional development. If teacher research aims at producing knowledge for the development of education, collaboration between different parties seems essential. Not only between teachers within the school but also between teachers and students, teachers of other schools, and parents. A very important aspect pertains to collaboration with academics around all aspects of the research process, which is essential for contributing to developing communities of research in teaching. Such collaboration should be viewed as professional development for all involved. Another implication for practice is the need to make results from teacher research accessible, and systematic attention should be paid to developing platforms where teachers can make their research results public, specifically for other teachers.

PAPER PRESENTATION

Improving competences of classroom management. Evaluation of a teacher training programme.

Valentina Piwowar, Free University of Berlin, Germany; Felicitas Thiel, Freie Universität Berlin, Germany; Diemut Ophardt, Freie Universität Berlin, Germany

The intervention study reports the evaluation of a training program for advancing competences in classroom management. Classroom management is a well established concept in US-American research, whereas there is a lack of empirical studies on teacher training in classroom management skills in Germany. The intervention is composed of three modules and contains theoretical input and the guided analysis of video recordings. 60 experienced secondary level teachers attended the program. The experimental group participated in all parts of the intervention whereas the experimental group received a shortened version. Effectiveness of the program will be assessed by direct and indirect measurements. Student, teacher and observer ratings were developed to measure the quality of classroom management. Additionally, the students' on- and off-task behavior is assessed as well as the acceptability of the intervention evaluated by the participants.

Theoretical Background

In German teacher education and training, building competences in classroom management was a neglected issue for a long time (Helmke, 2003). However, classroom management is a central process variable for student achievements (Wang, Haertel & Walberg, 1993; Brophy & Good, 1986) and therefore crucial for quality teaching. According to Ophardt & Thiel (2008), classroom management is constituted by three complementary approaches:- the behavioral approach focuses on encouraging desired behaviour and reducing misbehaviour,- the ecological approach refers to the works of Jacob Kounin (1970) and Walter Doyle (1984, 2006) and emphasizes proactive management techniques as smoothness, momentum or signal continuity,- the action theory is represented by Edmund T. Emmer, Carolyn M. Evertson and Carol S. Weinstein (Emmer, Evertson & Worsham, 2003; Evertson, Weinstein & Simon, 2006) and focuses on introducing and establishing efficient rules and procedures to formulate expected behaviour.

While in US-American research and literature the concept of classroom management is well established, there is a lack of German studies and data for an evidence based design of programs for conveying competences in classroom management in teacher education. Investigations of expertise in teaching evince that in addition to procedural knowledge partially unconscious routines are relevant for classroom management (Schlön, 1987). By analysing their own teaching behaviour, teachers become aware of their teaching competences. As Brophy (2004) points out, video based analysis is one of the most efficient methods that helps to develop the expertise pointed out above. The implementation of video documented lessons allows a specification and increase of personal knowledge and enables to reflect contextual conditions and alternative options of behaviour (Krammer & Reusser, 2006). Research aims Aim of the intervention study is the evaluation of a training programme for improving competences in classroom management. The programme contains the imparting of practice-oriented competences, establishing rules, preventing classroom disruptions, dealing with classroom disruptions and conflicts as well as effective classroom guidance strategies.

Method

Participants The study involves 60 experienced secondary level teachers who attend a programme that aims at improving their classroom management skills. Class sizes range from 8 to 31 students aged between 11 and 18 years.

Design

The effectiveness is measured with a quasi-experimental design: Participants choose themselves whether to participate in the experimental or control group. The experimental group received the described intervention (see

below), consisting of three parts, while the control group participated in a shortened version of the first and second part. In addition to the pre- and post-test, a follow-up will be realized four months after the intervention has taken place.

Intervention

The whole intervention is composed of three modules:

Module 1- Imparting declarative knowledge for central strategies of classroom management - Illustration of theoretical contents and important research findings by video examples

Module 2- Video extracts will be discussed in order to deepen the knowledge and develop the previously addressed strategies of classroom management - Explicating the practical knowledge and handling cognitive conflicts will be practiced by discussing contrastive examples

Module 3- Transferring newly acquired skills into practise and reflection in small groups- Video recordings from the participants' classes will be discussed in circles presented by a group leader for improving practical knowledge. Participants obtain a reader which contains the main aspects.

Material

The effectiveness of the programme will be measured by three objective and two self-report instruments. The objective measures contain a low-inferent student rating and an observer rating to quantify a teacher's classroom management skills. The ratings are based on the model of Ophardt & Thiel (2007). Furthermore, the Munich Observation of Attention Inventory MAI (Helmke, 1998), a standardized and systematic observation instrument, provides information about the frequency of students' on- and off-task behaviour. All raters were instructed in an intensive training course before using the observer rating and MAI respectively. A teacher self-rating is used to measure self-reported classroom management skills and knowledge on classroom management. Additionally, the professional self-efficacy is acquired (Schmitz & Schwarzer, 2000). Direct evaluation will be realized by a teacher questionnaire for the participants that facilitates the evaluation of the transfer of gained knowledge into practice, appropriateness of the exercises and quality of the seminar (organization and management).

Procedure

The described instruments are adopted in 60 secondary classes at each of the three times of measurement. In a first lesson, two raters are evaluating classroom management skills while the students' on- and off-task behaviour is assessed via MAI by one further rater. In a second lesson, students and teachers complete their ratings. Expected Data analysis By calculating a latent-change model, the amount of change on the level of performance as well as on the level of knowledge will be computed. It is expected, that only participants of the experimental group show improvement in their performance.

Prospects

The results of the evaluation will be presented and discussed.

PAPER PRESENTATION

Personalised teaching in Initial teacher education: school based activities and special educational needs

Hazel Lawson, University of Exeter, United Kingdom; Brahm Norwich, University of Exeter, United Kingdom; Tricia Nash, University of Exeter, United Kingdom

This paper reports initial findings from a research project which examined what and how PGCE trainee teachers learn about teaching pupils with special educational needs in their placement schools. The project addresses a gap in our understanding about the initial education of teachers as regards special educational needs (SEN), which has been source of concern for many years. Specifically the project examines the school based learning and outcomes of PGCE trainees in 6 primary and secondary university programmes in England that use different approaches to preparing teachers for the special needs aspects of teaching. Three kinds of school based approaches are examined: one that involves a practical teaching task (teaching a child with identified special educational needs), a second that involves a study of a pupil's learning (a pupil study task) and the third where there is no specific SEN task other than class teaching practice. Interviews, observations and survey questionnaires are used in each of the 18 participating schools (3 schools per programme). The research orientation enables a holistic and intensive analysis in each school based on a 2-3 day visit. The mixed data are analysed at a school level and then across the schools to draw out more general conclusions. The findings are used to identify practical principles and procedures about how to design and support planned school based activities relevant to learning to teach pupils with SEN.

Aims

The challenge for initial teacher training to prepare all teachers to teach a diversity of pupils, including children with special educational needs (SEN) and disabilities, is recognised internationally and given impetus from widespread moves towards inclusive education (Booth, Nes and Stromstad, 2003; Sharma Forlin and Loreman, 2008). In the UK (England), despite the Government's expectation that newly qualified teachers should be equipped to carry out their responsibilities, concerns have continued to be expressed about the inadequacy of initial training in this aspect of teaching (House of Commons, 2006, Ofsted, 2008).

This paper builds on recent work carried out by two of the authors (Nash and Norwich, 2010; Norwich and Nash, 2010) on a national project which conducted a trial and evaluation of a practical teaching task (SEN personalised learning task) for preparing primary and secondary teacher trainees to teach pupils with special educational needs. The evaluation of this trial underlined several key aspects, i. the challenge for initial teacher training to prepare all teachers to teach pupils with special educational needs, ii. the critical role of partnership between universities and practice schools in initial training and iii. the potential of ideas and practices about personalisation for including concepts about special educational needs pedagogy into wider pedagogic models.

The project reported here takes this work further by examining what and how PGCE teacher trainees, on their one year teacher training programme, learn about teaching pupils with SEN in the school-based part of their programme. The project has 3 specific aims:

1. To examine the context, the processes and the outcomes of PGCE trainees undertaking different planned SEN activities in primary and secondary schools in terms of school-university partnership arrangements and the schools' general arrangements for initial teacher training;
2. To compare the outcomes of undertaking a specific practical SEN teaching task for trainees and the schools over and above classroom teaching of pupils with SEN / disabilities with i. another kind of school based planned activity about SEN (such as a pupil study task) and ii. where there is only classroom teaching of pupils with SEN / disabilities;
3. To integrate the findings of this project into various forms that can be disseminated and communicated to PGCE providers, placement schools and other organisations with interests in teacher education, for example, to identify practical principles and procedures to design and support planned school based activities relevant to learning to teach pupils with SEN.

Methodology,

A detailed conceptual map was constructed to identify the areas for examination that included:

- i. Planned teaching task or other study task related to SEN;
- ii. Classroom teaching (planning, observation, teaching, supervision);
- iii. School's teacher training provision (supervision, support of trainees, seminars/presentations, place of SEN/inclusive teaching, roles of teacher training mentors/tutors, commitment to initial training partnership);
- iv. School's special needs and inclusive policy and practices (range, nature and incidence of additional needs, specialist resourced units, role of SEN Coordinator);
- v. School's overall policy and practice;
- vi. Partnership with PGCE provider (through visiting tutors, training of mentors/tutors, communication with university).

This framework was used flexibly to design the data collection methods (mainly qualitative with some quantitative aspects), that included documentary, observation and interview data. The participating schools were identified nationally as shown in the table below.

Overview of PGCE and school sample

The data were analysed using the starting conceptual framework but also by identifying emerging themes in a grounded way and summarised in school case analyses. These case analyses were then compared and contrasted to identify higher level themes and principles relevant to the research aims.

Findings:

This paper reports the analyses of the similarities and differences between participating schools as settings for the professional learning to teach pupils with SEN/disabilities. These analyses are set in terms of the partnership arrangements between the schools and the university providers and the schools' general arrangements for initial teacher training. How the trainees in these schools approached the planned school based tasks is also analysed in terms of the kinds of planned tasks compared to the schools with no planned teaching task.

Significance of the research: theoretical and educational:

The paper highlights some key issues in the initial professional learning of trainee teachers in a challenging area of teaching. This addresses both the school organisational and classroom pedagogic processes that improves our

knowledge and understanding about teacher education relevant to the special needs and inclusive education field. The paper will also contribute to practical knowledge about designing and supporting planned school based activities to enhance initial professional learning to teach pupils with SEN / disabilities.

PAPER PRESENTATION

Diversity at the start of teacher education?

Petra Herzmann, Universitat zu Koln, Germany; Johannes Konig, University of Cologne, Germany

Debates on the reform of teacher education in Germany underline the importance of evaluative information on teacher education programs, which is a challenge for empirical research. However, since the discussion on the effectiveness focuses on the output of teacher education, a question hardly taken into account is related to the diversity of candidates starting out to become a teacher: To what extent, for instance, do they differ in domain-specific learning preconditions right at the beginning of their teacher education? Such a question has to be taken into account when designing a new teacher education curriculum and correspondent evaluation designs. This presentation focuses on 56 future teachers who began their teacher education career in winter term 2009/2010, attending a new model program of educational opportunities to learn in teacher education at the University of Cologne. The model program is longitudinally evaluated with a range of quantitative indicators and qualitative instruments. An overview on the model program is given. First results from the first occasion of measurement on learning preconditions of future teachers are presented. Descriptive statistics and intercorrelations of various quantitative indicators are reported leading to the assumption of having a heterogeneous learning group. Empirical findings from qualitative evaluation give in-depth information on the diversity of future teachers and raise substantial questions about the design of adequate opportunities to learn in teacher education.

The introduction of and the current discussion on teacher education standards as well as the implementation of the BA/MA structure in teacher education according to the Bologna reform have led to a new understanding on how to design teacher education programs. Opportunities to learn and learning processes of teacher students, for example, are to be orientated towards professional tasks rather than structured by scientific disciplines (cf. Gehrman et al., 2010). Moreover, while the autonomy of universities regarding the design of teacher education programs has been increasing, evidence based information about strengths and weaknesses of specific programs implemented become more and more important at the same time. As a consequence, there is an increasing demand for evaluative information on recently designed programs or components in teacher education (Kßnig & Blßmeke, in press).
